surgical emphysema of the left side of the upper part of the chest and of the left side of the neck and face as high as the supra-orbital ridge, so that the left eye was partly closed by the emphysematous swelling. No bony crepitus could be made out after a further search in the chest. On percussion the chest was found to be normal except for a hyper-resonant note inside the left nipple. Coarse crepitations were heard with inspiration and expiration all over the chest, and during a pause in breathing fine crackling was heard over the heart and the presence of emphysema of the mediastinum inferred from this sign. There was no expectoration. The pulse-rate was 120 per minute, and the wave very easily compressible. The patient looked so ill that it seemed unlikely that he would live till morning. He was ordered a canopy and steam kettle, and half an ounce of brandy every three hours. Next morning (May 5th) he was more conscious and could feed himself when a cup of milk was put in his hand. He was cyanosed, with a respiratory rate of 44 per minute; the alæ nasi were working, and there was inspiratory recession of the lower intercostal spaces. There was marked rattling uniformly heard all over the chest and evidently originating in the larynx or trachea; no evidence of fluid or air in either pleural cavity was to be obtained. The pulse-rate remained at 120. In the evening there was inspiratory recession of the lower part of the thorax on each side, and less crepitation in the chest, so that the entry of air was evidently less. The respirations were 50, the pulse rate 144, the temperature 103·8°, and the surgical emphysema and left-sided weakness were unchanged. The patient passed a restless night, but next day was quieter, the pulse-rate being 180; the respirations gradually increased to 72 per minute, the temperature rose to 106°, and he became more cyanosed and died at 3·30 P.M. from asphyxia.

At the post-mortem examination the cranium and its contents were found to be normal except for congestion; there was no bruising of the scalp, no intracranial hæmorrhage or embolism, and no softening, though there was some flattening of the convolutions, especially of the right side. No fracture of the ribs or of the sternum was present, nor was there any dislocation of the rib cartilages or of the clavicles. There were ecchymosis and surgical emphysema of the mediastinum and parietal pericardium, and ecchymosis on the posterior surface of the heart, the valves of which were normal. Extending upwards vertically for two inches from the bifurcation of the trachea a rent separated the tracheal rings from the soft posterior wall on the right side, and was, therefore, intra-thoracic. Surrounding this rent was an abscess lying outside the trachea. The bronchi contained pus; the lungs were congested with a few patches of pneumonia; there was no air nor fluid in the pleural cavity; the abdomen was normal.

I am indebted to Mr. Page for permission to publish this case.

Devon.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—At a meeting of the Council held on Feb. 23rd Mr. D. B. Balding, F.R.C.S. Eng., chairman of council, presided. Dr. W. Gayton was elected treasurer, in the place of Mr. C. M. Frost; Mr. Arthur Greenwood hon. secretary, in the place of Mr. J. W. Barnes; and Mr. F. H. Oliver auditor, in the place of Dr. W. Smith. The office of the association was changed from 3, Bolt-court, Fleet-street, to 9, Copthall-avenue, London-wall, E.C., the offices of Messrs. Beckingsale and Co., solicitors to the association. It was unanimously resolved that the passing of the Poor-law Officers' Superannuation Act had by no means rendered the further existence of this society unnecessary, and that it was highly desirable that the Poor-law medical officers of England and Wales should still have an association to watch over and protect when necessary their special interests in the somewhat serious differences which of necessity occasionally arise between them and the various boards under which they hold office. Application was made by several public vaccinators that counsel's opinion should be taken respecting the legal position of those officers under the recent Superannuation Act, and after some discussion it was resolved that one-third of the cost of putting a case before some eminent counsel should be defrayed by the association if the remainder were subscribed by those of the class interested.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

RECOVERY AFTER TAKING 1 oz. OF CHLORODYNE AND 250 GRAINS OF SULPHONAL.

BY KEITH CAMPBELL, M.B. EDIN.,
ASSISTANT PHYSICIAN TO JAMES MURRAY'S ROYAL ASYLUM, PERTH.

A MAN was lately admitted to this asylum who had for months suffered from insomnia, for which he had got sleeping draughts containing chloral hydrate. Owing to business anxiety the insomnia got much worse and his general health broke down. His power of self-control was also diminished. He went on a visit to a relation at the seaside, and on Jan. 11th, 1897, he took the boat to a neighbouring watering-place, where he bought an ounce bottle of chlorodyne. He went on board the next boat and took the whole of this. He got off at the next stopping place and bought at two separate druggists two bottles of sulphonal tabloids, each containing twenty-five tabloids with five grains of sulphonal. He had thus 250 grains of sulphonal in his possession. He was now feeling dazed and utterly reckless, and he went to an hotel, took a bedroom, and ordered hot water to be sent up. He mixed and took the whole of the sulphonal. This was in the afternoon of a Monday. He remembers nothing more till the morning of the following Thursday, when he had some breakfast. It was afternoon, however, before he could give directions for a telegram to be sent to his friends, under whose care he went home next day. From Sunday night till next Thursday morning he had just one cup of bovril. On admission as a voluntary patient on the following Monday he was in a state of nervous breakdown, restless, unable to sustain any effort, querulous, and irritable. He looked ill and worn. There was considerable gastric catarrh, and his urine contained a large amount of sugar. His pupils were unequal. He is an undersized man with a highly neurotic family history. In a week, under appropriate treatment and diet, the sugar disappeared, and his general health is now very fair.

Two cases of larger doses of sulphonal have been recorded. The first case was when thirty grammes (463 grains) were taken, causing 114 hours' sleep with a short interval, no bad effects resulting.[1] In the second case, reported in THE LANCET by a Berlin correspondent, the same dose was taken by a workman, who slept thirty hours and after a short interval twenty hours. In neither case was any other drug taken. In the present case the drugs were bought at three different druggists in two towns in which the patient was a stranger, so that it is almost impossible to check the facts. The patient was perfectly frank about it, however, and related the whole circumstances clearly and without any bravado. At the time of taking the drugs he had no idea of what quantity he was taking; he only knew it was a large dose. Short of absolute certainty, there is every reason to believe that his statements are quite reliable.

Perth.

A CASE OF RUPTURED UTERUS.

BY PTOLEMY A. COLMER, M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.,
HON. SURGEON TO THE YEOVIL DISTRICT HOSPITAL.

I WAS called at 10 P.M. on Jan. 28th to attend a very stout woman, aged forty years, in her fifteenth confinement. I found the os about the size of a five shilling piece, with head presenting, the membranes ruptured, and pains occurring about every seven or eight minutes but not sharp. The patient was up and walking about, in fact, she told me I was not wanted yet. I left, giving instructions to call me again when the pains became frequent and more severe. I was

[1] THE LANCET, May 4th, 1889, p. 915.

Hosted by Google

called again at 3 A.M. on the 29th, and on entering the room noticed how ill the patient (who was now in bed) looked. On examination I found the chin caught on the perineum and with very slight traction, with the finger in the mouth it easily slipped out, and with a little more traction the rest of the body of a fine male child in a very advanced state of putrefaction was born. The placenta was easily expelled with a large clot. The uterus contracted well and there was very little hæmorrhage. The patient now began to complain of faintness, but no pain. Her pulse was quick and extremely feeble, and she had an anxious expression. I kept my hand on the uterus which appeared to keep well contracted and there was very little hæmorrhage. About 4.20 A.M. she seemed to rally, her pulse improved and she expressed herself as feeling better, but a quarter of an hour later the pulse became quicker and smaller and the breathing hurried and shallow. The patient, who showed extreme restlessness now began to get blanched and at about 5 10 A.M. she died. Immediately after death on introducing my hand into the uterus (which had just become flabby) I found coils of intestines and blood clots and could even feel the liver. No post-mortem examination was allowed. I may add that out of her fifteen confinements the patient had had only three natural ones, the rest being instrumental; one or two had been transverse and several had been breech presentations. There appeared to be no pelvic contraction. This case illustrates how obscure the symptoms of rupture of the uterus may be, as I was quite unable to find anything to account for her extreme prostration until the ast moments of life.

Yeovil.

NOTE ON A CASE OF LICHEN PLANUS CURIOUSLY AFFECTING SCRATCHES.

BY R. W. INNES SMITH, M.B. EDIN.,
LATE RESIDENT ASSISTANT MEDICAL OFFICER, ANCOATS HOSPITAL, MANCHESTER.

ON Feb. 13th I saw a woman, aged thirty-eight years, married but having no family, who complained of an eruption on the wrists, backs of the hands, the forearms, and the front of the right thigh. The eruption was generally typical of lichen planus. It consisted of discrete papules, the surfaces of which were flattened and often glazed. In some places the papules had run together, forming thickened patches with a small amount of scaling. There was some itching, but the patient complained more of a "tingling" sensation, especially when the papules were in their early stage. The eruption was first noticed by the patient last December on the inner aspect of one wrist. The curious point of this case, however, was that in places where the skin had been scratched each scratch had taken on the type of the eruption, and thus appeared as a raised, reddish, polished "line," composed of papules running together. Thus on first looking at the case these "lines" appeared as the more important part of the lesion, but from their general arrangement were easily recognised as the positions of old scratches. A further point in the case was that after a scratch was inflicted it seemed to heal in the usual way, leaving, however, a faint line, which was best seen on putting the skin on the stretch, this "line" gradually becoming developed into the condition described above.

The cause seems difficult of explanation. The patient herself traces the first affection of the scratches to "washing a cat which had skin disease," the animal retaliating by scratching her forearms and hands severely. This happened some weeks after the first appearance of the rash. It seems, however, to be merely a coincidence, as undoubtedly many of the scratches are the patient's own production. Possibly there is a parasitic element in the disease which would explain this peculiar affection of the scratches.

Duncan-terrace, N.

HEALTH OF LLANDRINDOD WELLS.—At the last monthly meeting of the Llandrindod Wells urban district council Mr. F. H. Roberts, the medical officer of health, presented his annual report for 1896, from which it appeared that the death-rate had been 8·27 per 1000 and the birth-rate 26·3 per 1000. Mr. Roberts referred approvingly to the sewerage extension scheme now contemplated at a cost of £6000, and to the electric light installation which is being laid down.

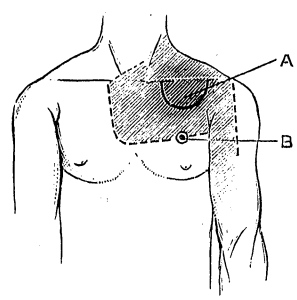
MIDDLESEX HOSPITAL.



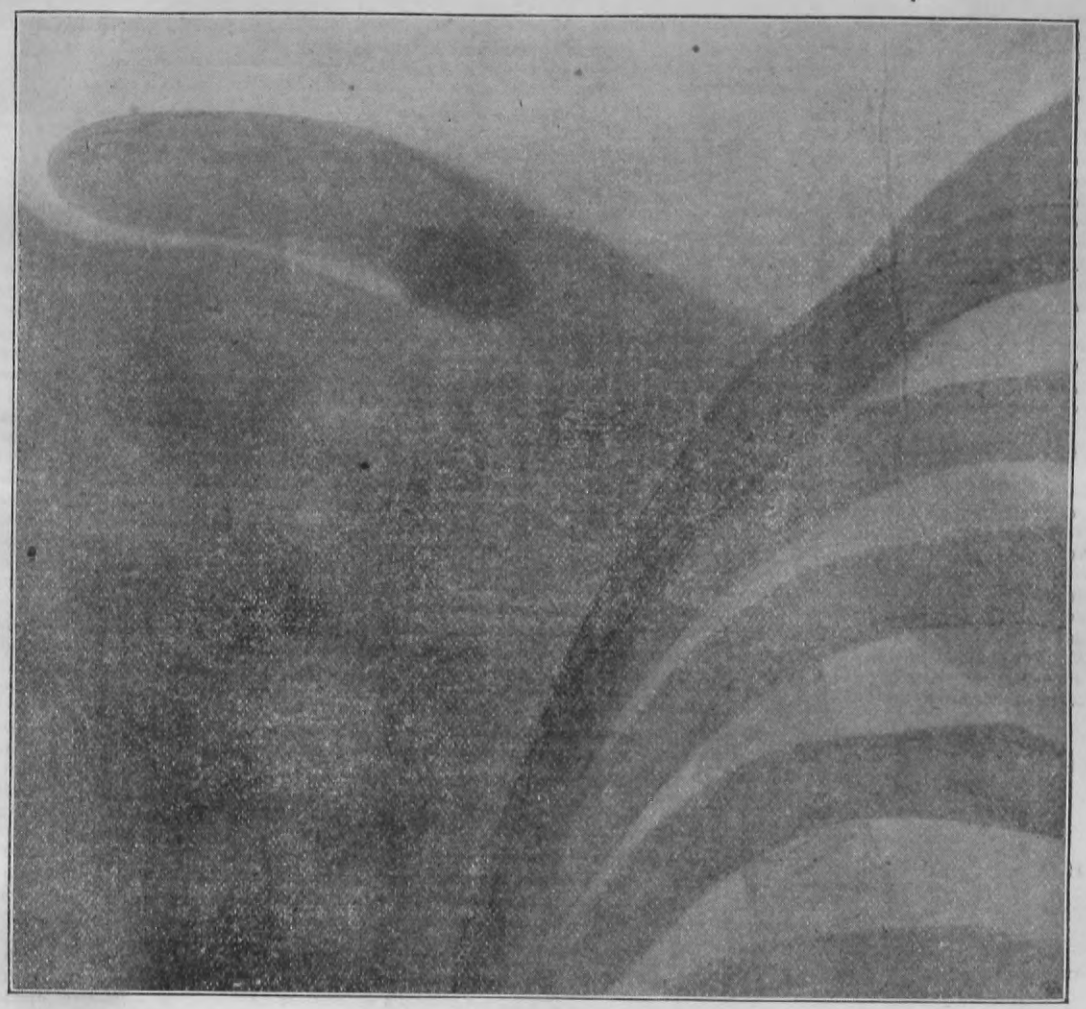
BULLET LODGED BEHIND THE CLAVICLE DETECTED BY MEANS OF THE ROENTGEN RAYS, AND CAUSING SYMPTOMS LIKE THOSE OF ARTERIO-VENOUS ANEURYSM.

(Under the care of Mr. HENRY MORRIS.)

FOR the notes of this case we are indebted to Mr. W. D. Perry, house surgeon.

The patient, a young man aged twenty years, was admitted to the Middlesex Hospital on May 11th, 1896, with a self-inflicted wound from a revolver bullet on the left side of the chest. On admission he had lost a large quantity of blood and was in a very collapsed condition. The bullet had entered at the upper border of the third rib three inches from the left border of the sternum and had then apparently passed upwards and inwards towards the root of the neck, but it could not be felt. Hæmorrhage had ceased when he was brought to the hospital, but there was a large quantity of blood effused beneath the pectoral muscles. No pulsation could be felt in the left radial and axillary arteries. On placing a stethoscope over the upper part of the chest on the left side there could be heard a loud roaring bruit, which was rather louder during the heart's systole, but continuous throughout diastole. It was most distinct at a point half an inch below the clavicle and two and a half inches from the left border of the sternum, and could be traced upwards into the supra-clavicular fossa, inwards across the chest to the right border of the sternum, and outwards along the line of the axillary and brachial arteries to a point midway between the shoulder and the elbow-joint, and more faintly even down to the elbow. (See diagram, Fig. 1.) It could be heard

FIG. 1.



A, Point where bruit was loudest. B, Point of entrance of bullet. The bruit was heard over the whole of the shaded area.

on the chest above a line drawn transversely from the wound, but not below it, and disappeared entirely when the subclavian artery was compressed. Shortly after admission the hæmorrhage re-commenced and was so severe as to lead one to think that the subclavian artery had been wounded. However, after compressing the proximal side of the subclavian artery the hæmorrhage ceased. About two hours after the injury was inflicted the patient was placed under an anæsthetic and an attempt was made to find and extract the bullet, but without success. The wound was enlarged and the track searched both by means of bullet-searchers and the little finger. The loud, roaring, and rasping bruit pointed to some injury to the subclavian vessels, and was very similar, indeed, to the sound produced when a communication between artery and vein exists. Whilst under the anæsthetic a feeble pulsation in

Hosted by Google

the artery at the wrist was felt. Under treatment the wound healed rapidly, and though there was a numbed feeling in the second and third fingers of the left hand, which only lasted for two days, no symptoms of importance developed. The pulse in the left radial artery began to return shortly after admission, and a fortnight later was quite distinct but feebler than the pulse at the right wrist. During the month succeeding admission the patient complained of attacks of pain shooting down the left arm, but not traceable along the course of any of the large nerve trunks. After the wound had healed and the patient had become convalescent several attempts were made to localise the bullet by means of the Roentgen rays, and on July 3rd a very satisfactory photographic negative was obtained. (See Fig. 2.) This showed the bullet to be lodged exactly behind the clavicle, about one and a half inches from the acromio-clavicular joint. At this time the condition of the bruit above mentioned was much the same as before. The left radial pulse was distinctly weaker than the right, but synchronous with it. There was no impairment of sensation in any of the fingers. On the 8th the patient was anæsthetised, and an incision made along the upper border of the clavicle about three inches in length, the outer end reaching to the inner margin of the clavicular attachment of the trapezius muscle. A careful dissection was made behind the clavicle, and the bullet felt lying rather beyond the outer end of the incision behind and below the edge of the trapezius. The incision was prolonged outwards for half an inch and a few fibres of the aforesaid muscle were divided, which enabled the bullet to be extracted without difficulty. (Fig. 3.) The wound healed by first intention, and the patient left the hospital on July 21st quite well. The bruit, however, had not altered in character, and the difference in the radial pulses was as marked as before. On July 31st the patient was again seen. The bruit was much the same as before, but very little difference could then be detected in the size of the pulses in the radial arteries of the two sides. No œdema, coldness, or numbness of the left forearm and hand had been observed nor any distension of the veins of the limb. With the persistence of the loud bruit and the similarity of it to that heard in cases of aneurysmal varix one was led to expect the development of some aneurysmal condition in the future. As the patient is not now living in England, it has not been possible to make an examination of his present condition, but a relative informs us to-day (Feb. 26th, 1897) that he has recently married, has never been in better health than he is now, that during the late summer and autumn he was rowing on a river, and all the present winter has been carrying on his business. There is, therefore, every reason to believe that there does not exist a direct communication, even of small size, between the artery and vein.

MISSION HOSPITAL, KASHMIR.

A CASE OF RENAL IRRITATION SIMULATING CALCULUS OF THE KIDNEY CURED BY NEPHROTOMY.

(Under the care of Dr. ERNEST F. NEVE.)

MOST surgeons of experience have met with cases in which renal pain was thought to be due to calculus, where subsequent operation has relieved the symptoms for which treatment was sought, but has not shown the presence of a stone. In some instances no stone has been found, although it was present, in consequence of imperfect search; the stone has been small and placed in the substance of the kidney, or it has been fixed in a deeply lying calyx. Careful and systematic search is required, but we have seen a small calculus escape detection altogether by skilled hands until the kidney was fully incised after nephrectomy. Mr. Greig Smith[1] puts the proportion of failures to find a stone as one-fifth of the operations undertaken for the purpose of nephrolithotomy. Mr. Jacobson[2] gives the following list of the chief conditions which simulate renal calculus: (1) lithiasis; (2) tuberculous kidney; (3) slight pyelitis; (4) moveable kidney; (5) aching kidney; (6) nephralgias due to disease in parts adjacent to the kidney; (7) gall-stones retained in the gall-bladder; (8) spinal disease; (9) interstitial shrinking nephritis; and (10) new growth of kidney in its early stage. It is, however, only necessary to mention most of these to prevent anyone exercising ordinary care, from making a mistake in diagnosis.

A native, aged forty years, had complained for three years of periodical attacks of severe renal pain. His general condition was good. The urine was loaded with oxalate crystals and showed traces of pus. There was distinct but slight tenderness on pressure over the right kidney. On Oct. 7th, 1895, I made an incision four inches long almost horizontally backward from the tip of the last rib. Displacing the ascending colon and peritoneum forwards, the kidney was found after some searching, and was exposed by scraping through the fat with the finger. No stone could be detected on palpation. There was a little doubt as to whether, on needling, a slightly gritty-feeling area was traversed. On incising the pelvis and sounding systematically there was no sign of stone. The renal wound was stitched, also that in the loin, a drainage-tube of small calibre being left in. This was gradually shortened, and finally removed on the twenty-second day. The patient was dismissed on May 1st, 1896, free from pain, having had no return of his old symptoms.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Annual Meeting.

THE annual general meeting of this society was held on March 1st, the President, Dr. HOWSHIP DICKINSON, being in the chair.

The report of the Council was read. The report showed the flourishing state of the society, a record number of forty-eight Fellows having been elected during the year. The death roll had also been unusually heavy, twenty-five Fellows having died during the twelve months. The arrangements for converting the original 4 per cent. debenture loan into 3 per cent. debentures had been satisfactorily accomplished, and would result in a saving to the society of about £350 per annum.—After some remarks by Mr. T. HOLMES and Dr. THEODORE WILLIAMS the report was adopted.

The PRESIDENT, in his annual address, referred with satisfaction to the success of the conversion of the loan. The dinner at the Hotel Cecil, which is a new departure, had been a success, and he hoped that it would become an annual institution. The customary obituary notices of deceased Fellows closed the address, special reference being made to the lives of Professor Du Bois Reymond, Sir J. Russell Reynolds, Sir George Humphry, Sir George Johnson, and Mr. George D. Pollock.

After the usual votes of thanks had been passed the officers and council were elected to serve during the ensuing year. The following list was chosen: President: William Howship Dickinson, M.D. Vice-Presidents: William Marcet, M.D., F.R.S.; James Edward Pollock, M.D.; Frederick James Gant; and Charles Sissmore Tomes, F.R.S. Honorary treasurers: William Selby Church, M.D., and J. Warrington Haward. Honorary secretaries: Norman Moore, M.D., and Robert William Parker. Honorary librarians: Samuel Jones Gee, M.D., and Rickman J. Godlee, M.S. Members of Council: John Abercrombie, M.D.; Robert Leamon Bowles, M.D.; John Mitchell Bruce, M.D.; David Ferrier, M.D., F.R.S.; Joseph Arderne Ormerod, M.D.; William Watson Cheyne, F.R.S.; Henry Hugh Clutton; Frederick S. Eve; William Appleton Meredith; and Robert Alexander Gibbons, M.D.

PATHOLOGICAL SOCIETY OF LONDON.

Exhibition of Cases and Specimens.—Epithelioma of the Penis.—Changes in the Sub-maxillary Gland Secondary to Cancer of the Mouth.

A MEETING of this society was held on March 2nd, Mr. BUTLIN, the President, being in the chair.

Dr. F. J. SMITH and Mr. J. H. TARGETT showed a case of Aneurysm of the Aorta in a boy eight years of age. There was practically no history, the boy having been suddenly seized with dyspnœa only a few hours before his death, which occurred almost immediately after his admission to hospital. Post mortem a sacculated aneurysm the size of an orange was found projecting backwards from the upper part of the descending arch of the aorta and pressing on the œsophagus. The heart and œsophagus were perfectly free from disease, and to the naked eye the inner coat of the aorta was not degenerated. There was, however, a stenosis of the aorta, apparently congenital, just beyond the origin of the left subclavian artery; but as this was on the cardiac side of the aneurysm it was not easy to see what part the stricture could have played in the formation of the aneurysm.—At the suggestion of the PRESIDENT the specimen was referred to the morbid growths committee.

Dr. CYRIL OGLE showed a specimen of Dermoid Growth with Invasion of the Lung. The specimen was removed from the body of a man, twenty-eight years of age, who died from profuse hæmoptysis. He had suffered intermittently from cough and hæmoptysis for five years. On admission the temperature was hectic and the expectoration fœtid, the physical signs suggesting empyema. At the necropsy a cavity about four inches in diameter was found in the lower lobe of the right lung, which communicated freely with the middle primary division of the bronchus. It contained: (1) offensive grumous pus; (2) cheesy material, evidently sebaceous; and (3) five or six cream-coloured bodies like swollen digits, flabby, and covered with skin and fine hairs. Their attached ends were fused together into a firm mass which could be traced through the wall of the cyst, and was continuous with a mass which reached forward into the anterior mediastinum. Embedded in the central core was a large tooth. A microscopic section of one of the tongue-like processes showed a covering of stratified epithelium over a stroma of fibrous tissue containing some fat cells. There was evidence of inflammation near the surface only.—Mr. GODLEE said that these rare tumours did not appear to give rise to symptoms till adult life, and that then the symptoms were often those of empyema, and a purulent effusion did occur. In a case he had observed the symptoms began acutely in adult life, with expectoration of pus containing a few hairs. A few years later an incision was made into the cavity, which contained the same finger-like processes and some long hairs. The cyst was lined by a membrane exactly similar to that covering the digitations. In another case the symptoms commenced suddenly with a pleural effusion, at first serous and afterwards bloody. Later a tumour formed at the ensiform cartilage, and an incision liberated thick brown pus and greasy matter, possibly sebaceous. The wound ultimately healed, but later a fresh sinus formed near the clavicle and discharged for some time, but at length closed.

Mr. HUTCHINSON and Mr. E. FRAZER read a paper, with lantern demonstration, on Epithelioma of the Penis. They

Hosted by Google

pointed out that the clinical features of different forms varied considerably, and that several varieties might be distinguished. Of these the chief were—(1) the warty or papillomatous form; (2) the fungating form; (3) the flat disc or indurated ulcer; (4) the purely eroding or destructive form; and (5) carcinoma of the urethra. In the usual varieties starting on the glans penis, or inner aspect of the prepuce, it was shown that, however extensive the growth was, the urethra and corpora cavernosa were but rarely invaded, and hence the deduction was made that amputation at the root of the penis by the Thiersch-Gould method was only indicated in exceptional cases. Microscopically the malignant growths of the penis were shown to differ as greatly as the naked-eye appearances. The large squamous-celled epithelioma with cell-nests is the commonest; another variety is the large alveolar type without cell-nests, a third the small alveolar with tendency to assume a tubular appearance, and as a rare occurrence a small-celled carcinoma starting in the urethra. Evidence was adduced in favour of the belief that the last named might start in the glands opening into the fossa navicularis, &c. The frequent occurrence of cyst-like spaces, lined with smooth epithelial walls and containing leucocytes and free, swollen, epithelial cells, was illustrated from six different cases of epithelioma of the penis, and their origin was discussed. Such cyst-like spaces in the epithelial down-growths were found in cancer of the vulva sometimes, and comparatively rarely in epitheliomata of other parts of the body.—The PRESIDENT said that the malignancy of epithelioma of the penis did not rank high. He agreed that complete ablation was not necessary unless there was direct involvement of the parts at the root.—Mr. TARGETT thought that the cystic changes which had been described occurred in other parts besides the penis—as, for instance, in epithelioma of the gum. The surrounding inflammation was due to septic infection with pyogenic organisms.—Mr. SHATTOCK was also familiar with cyst formation in squamous epithelioma in other parts. In his cases the cysts were found to be due to degeneration of the cells themselves, and there were no signs of inflammation. He agreed that involvement of the corpora cavernosa was very rare, but there was one specimen in the museum of St. Thomas's Hospital in which there was quite a horny mass in the corpora cavernosa.

Mr. J. HUTCHINSON, jun., and Mr. E. FRAZER exhibited specimens of Inflammatory Changes in the Sub-maxillary Gland occurring with Epithelioma of the Tongue and Floor of the Mouth. Part or the whole of the gland may become replaced by fibrous tissue and lymphoid cells, the alveoli of the gland undergoing atrophy and largely disappearing. These changes are perhaps due to irritation of the gland from pressure on Wharton's duct, and are of clinical interest from the induration which they cause being liable to be mistaken for secondary deposits of the growth. The actual invasion of the salivary gland by deposits of epithelioma in the lymphatics in the former was also discussed.—Mr. CECIL BEADLES said that he had examined seventeen specimens of sub-maxillary gland from cases of cancer of the mouth. In only one was the enlargement found to be due to actual epitheliomatous deposit.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A CLINICAL meeting of this society was held on Feb. 26th, the President, Dr. BUZZARD, being in the chair.

Dr. SAMUEL WEST showed a case of Unusual Syphilitic Eruption in an Infant. The child was in good health till she was eight months old. She then had a number of concentric patches on both cheeks, which began as circular spots and spread at the periphery. She had a group of condylomata at the anus, and there was also a general lichenous eruption which had probably no connexion with the other skin lesions. The patches increased in size for a time, but ultimately healed without leaving a scar. Fresh patches appeared while the child was under treatment, and pursued a similar course to the older ones. He thought it was a rare case of syphilitic eruption, although there was not much direct evidence of its specific nature. An exactly similar case was figured by Hutchinson in his Atlas.

Dr. COUPLAND showed a young man with Multiple Neuromata, Osseous Growth of the Frontal Bone, and Nervous Symptoms of doubtful origin. The neuromata were of varying size, fifteen in number, and situated in the subcutaneous tissues of the arms and trunk, the largest being about three inches long. They had been noticed since he was ten years of age. The osseous growth projected from the left side of the frontal bone and had been growing for the last three years. During the last twelve months curious nervous symptoms had shown themselves. There were loss of memory and some general mental alteration, a curious high-pitched voice, staggering gait, total deafness of the left ear, some weakness of the left arm and left side of the face, and double optic neuritis. There was also proptosis of the right eye, which was probably due to the high degree of myopia present (−15 D). He had difficulty in deciding whether the nervous symptoms were due to neuromata involving the cranial nerves and spinal roots or were associated with the tumour of the frontal bone.

Dr. F. PARKES WEBER showed a case of Aortic Stenosis with Bradycardia. The patient was a young man suffering from persistent dyspnœa and syncopal attacks. For some months there was a systolic aortic murmur only, but during the last few days a diastolic murmur had developed. The pulse-rate was persistently slow. The aortic dulness was higher on the right side than the left, but he thought that this was due to general enlargement of the right side of the heart rather than to an aneurysm. There was a history of syphilis many years ago, but the symptoms came on rather suddenly soon after an injury. — Dr. ORMEROD referred to a case of Aortic Stenosis in which a diastolic murmur appeared after the patient had been under observation for many months. — Dr. S. WEST mentioned the case of a man, thirty-five years of age, with signs of Aortic Stenosis and whose pulse-rate was seldom over thirty. He was under observation for several years and did not develop a diastolic murmur.—Dr. A. MORISON said that in cases where there was bradycardia there was usually good compensation; and dyspnœa, such as this patient showed, was very unusual in association with it.

Dr. ALBERT WILSON showed a girl, fifteen years of age, who exhibited Dual States of Consciousness. The case was exhibited before the society a year ago. The symptoms had followed an attack of what was believed to be meningitis attended with maniacal excitement. In her normal state she was bright and intelligent, in the abnormal stage she was semi-imbecile and infantile in her ways and her mode of expressing herself, and appeared to be almost blind, although there were no ophthalmoscopic changes. During this abnormal period she showed some capacity for drawing, although she had none in her normal state. She passed abruptly by turns from one stage to the other, and when in the normal condition had no recollection of the events which had happened in the abnormal stage.

Dr. ST. CLAIR THOMSON showed a man, thirty-three years of age, with a Hæmatoma of the Antihelix of the left Auricle which had developed spontaneously. It subsided without the scarring that was usual in insane cases. He exhibited a photograph of an ancient bronze statue of a pugilist armed with a cestus whose ears showed signs of many hæmatomata. — The PRESIDENT pointed out that there were no signs of general paralysis, the pupils being equal and reacting normally, and the knee-jerks were not exaggerated.

Dr. BEZLY THORNE showed a case of Aneurysm of the Aorta treated by mineral baths, graduated walking exercises, and free ingestion of fluids. When he commenced treatment in November, 1896, the patient had increased cardiac dulness, tumultuous action of the heart, and great dyspnœa on the slightest exertion. After six weeks he could walk with comfort. The apex beat was one and a half inches nearer the sternum, but there was not much diminution in the dulness to the right of the sternum. A skiagraph showing the outline of the aneurysm was made by Dr. Campbell Thomson before and after the treatment, and showed that in spite of the exercise allowed there was no increase in its size. There had been some recurrence of the symptoms, which had at once yielded to the same treatment.

Dr. FLETCHER LITTLE showed a case of Raynaud's Disease occurring in an otherwise healthy young woman, nineteen years of age. After having been subject to attacks of blueness of the fingers for some months, she was attacked during the cold weather with gangrene of the index, middle, and ring fingers of both hands The toes were unaffected. The cheeks were somewhat thickened and sclerodermatous. The association of scleroderma with Raynaud's disease was noticed by

Hosted by Google

Raynaud himself, and the observation was confirmed by Dr. Coupland. Relief had been afforded in this and another similar case by the administration of nux vomica.

Dr. S. WEST showed a man, thirty-nine years of age, who had suffered from Weakness of the Arms for two years. The deltoids and the muscles around were strong and well developed, and the muscles of the hands were unaffected. The muscles of the arm and forearm, however, were very weak and much wasted. A few of the muscles in the forearm showed the reaction of degeneration imperfectly. He inclined to the view that it was a case of myopathy rather than one of progressive muscular atrophy.

Mr. F. C. WALLIS showed a new method of treating an Intractable Ulcer of the Leg. The ulcer had increased in spite of the ordinary treatment. He found that Thiersch grafts were not successful when implanted on the surface of a chronic ulcer. He therefore made two long parallel incisions a little distance from the borders of the ulcer, and having separated the skin from the subjacent tissues he was able to bring the edges of the ulcer together. Two gaps were thus made at the site of the lateral incisions, and these he had filled by Thiersch grafts. So far the results were satisfactory.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Royal Commission on Vaccination.

A MEETING of this society was held on Feb. 19th, Dr. G. P. BATE, President, being in the chair.

Dr. ARMSTRONG resumed the discussion on the recommendations made by Dr. Bond at the last meeting (Jan. 15th) by calling attention to the amount of insufficient vaccination, which was for all practical purposes no vaccination at all. He considered that the society should take up the matter seriously, impressing the fact upon the Legislature especially in reference to the report of the dissentient members of the Royal Commission, who studiously ignored degrees of sufficiency—indeed, if uniformity could not otherwise be secured he would have the practice of vaccination restricted to responsible public officers.—Dr. NEWSHOLME thought that one advantage accruing from the postponement of the operation would be that the eruptions so frequent in early infancy would have already appeared, and therefore would not be, as they were now, on the *post ergo* principle, ascribed to vaccination.—Dr. MITCHELL WILSON (Doncaster) looked on the demand for better inspection of common lodging-houses as a reflection on the officials of the sanitary authorities unless it involved the power to re-vaccinate, which they had not at present. But in workhouses, where the guardians could enforce labour, &c., their compulsory powers might be extended to include vaccination, for the tramp in the casual ward was in a different position from the free man in a lodging-house.—Dr. ARMSTRONG interposed that the tramp on the tramp was more dangerous than he was in the workhouse or lodging-house.—Dr. BOND complained that, so far from encouraging the use of calf lymph, the Local Government Board resented frequent applications for it.—Dr. RENNER followed on the same lines, expressing his preference for glycerised lymph, which was used long ago in Italy and which Dr. Copeman had shown improved, instead of deteriorating, by keeping. All vaccinations should be inspected on or before the eighth day, after which it was no longer possible to complete an imperfect success by additional insertions.—Dr. COPE, approaching the subject from the standpoint of the public vaccinator, maintained that the station system could not be superseded. Much might be said in favour of home vaccination, but it would impose great trouble on the public vaccinator, and he would appear as a tout and a rival to other medical men. The school was still more objectionable; he would there come into collision with the officials of the School Board and Education Department, and with absence, evasion, or actions for assault. At the stations publicity made the parents civil and the infants clean, and their retention was necessary for the teaching of students. The Vaccination Officers' Association had for twelve years pressed on the Local Government Board most of the recommendations now put forward by the Commissioners.—Dr. WILLOUGHBY said that both in the press and at the meetings of the society he had pleaded for a form of certificate that should indicate the degree of success obtained, but that this should be expressed by the number of vesicles, which could always be counted, rather than by their aggregate area, which it was impossible to verify after the lapse of years; besides the lessened risk of wound infection from delayed healing when numerous small vesicles were substituted for a few large abrasions. He insisted on the importance of re-vaccination about the age of puberty, without which the operation should be considered as only half performed. It was to forty years of this practice that the city of Frankfort enjoyed immunity from the epidemic that during the Franco-German War ravaged the rest of Germany and Europe, and to its adoption throughout the empire was due the almost complete extinction of small-pox in Germany, the deaths in that country having for some years past been as 1 to 100 in Switzerland, 110 to 120 in England, 260 in France, and 640 in Holland, and even these were mostly those of foreigners or on the frontiers of Russia and France, and the victims of the imported infection were for the most part infants not yet vaccinated or persons who, born before 1860 and not having passed through the army, had escaped re-vaccination. He approved the use of calf-lymph as a concession to popular prejudice only, and not from any belief in its superiority. But he would urge on the Institute of Preventive Medicine and the Local Government Board the duty of producing and supplying new strains of lymph obtained by variolation of the cow, as had been done by Voigt of Hamburg in 1881, and subsequently by Haccius, Fischer, King, Simpson, and others, and the superiority of which was shown by the fact that whereas in Germany generally 97 per cent. of the legal re-vaccinations were successful, in Hamburg, where Voigt's lymph had been almost exclusively used since 1882, the majority of native children were as yet insusceptible.

Dr. BOND replied shortly to each of the preceding speakers, expressing his belief that the difficulties of home and school vaccination had been exaggerated.

HUNTERIAN SOCIETY.

Torticollis and its Treatment.

A MEETING of this society was held at the London Institution on Feb. 24th, the President, Dr. G. E. HERMAN, being in the chair.

Mr. VICTOR HORSLEY delivered the second Hunterian Society Lecture and chose for his subject "Torticollis and its Treatment." He first enumerated the different forms of torticollis and gave a description of each, and then gave an account of their causation and of the experimental evidence as to their production. The treatment by drugs, electricity, and surgical methods suitable to each form was dwelt upon. The lecture was illustrated by several photographs thrown on the screen by limelight. At the conclusion of the lecture a hearty vote of thanks proposed by the PRESIDENT was carried unanimously.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Retention of Menstrual Blood.—Puerperal Septicæmia Treated by Tincture of Digitalis.

A MEETING of this society was held at the Medical Institution, Liverpool, on Feb. 19th, Dr. ARCHIBALD DONALD, Vice-President, being in the chair.

Mr. E. STANMORE BISHOP showed: (1) Fibroid Uterus with Cervical Carcinoma, removed by vaginal hysterectomy; (2) Fibroid Uterus with Double Cyst, removed by vagino-abdominal section, ligature of the lower half of the broad ligaments was the first step and the operation was completed by suturing the vaginal opening and no drainage of the abdominal cavity; (3) Dermoid Cyst, removed by abdominal section from a girl aged fourteen years; and (4) Ovarian Abscess with Fibroid Uterus.

Dr. LLOYD ROBERTS showed: (1) A portion of a Lead Pencil removed from the Bladder of a married woman aged thirty-seven years. The pencil shown was a "stub" of an ordinary long lead pencil measuring two and a half inches in length and deeply encrusted with a phosphatic deposit. At the part least mutilated by the forceps in removal the diameter of the foreign body—pencil and crust—was rather more than half an inch. (2) Left Ovary and portion of the Fallopian Tube removed by posterior vaginal cœliotomy. The ovary was

Hosted by Google

the size of a Tangerine orange and cystic, and was firmly adherent to surrounding structures.

Dr. T. B. GRIMSDALE showed the Fallopian Tubes removed by abdominal section for Tuberculous Salpingitis. The tubes were studded with miliary tubercle in their peritoneal covering and distended with fluid; they measured six inches in length and were of about the thickness of the index finger. The fimbriated end of the tube was enlarged.

Dr. ARTHUR WALLACE read notes of a case of Retention of Menstrual Blood in the Right Imperforate Half of a Septate Vagina and Uterus Bicornis et Bicollis. The patient was aged twenty-two years. Menstruation commenced at sixteen years, and she was regular. There was a swelling in the abdomen occupying the right iliac, lumbar, and umbilical regions, and measuring four inches in diameter. *Per vaginam* a swelling was felt which appeared to lie outside the vaginal wall on its right side and to be continuous by a constricted portion with the abdominal swelling, forming a dumb-bell-shaped swelling. The vaginal swelling was tapped and eighteen ounces of treacle-like blood escaped, after which the cervix was felt high up behind and to the left of the swelling, and the sound passed three inches.

Dr. GLYNN WHITTLE read a paper describing ten cases of Puerperal Septicæmia treated by tincture of digitalis, the primary aim being direct control of the pulse. An accompanying benefit, but one following as a secondary result, was relaxation of tonic contractile spasm of the sphincter at the os uteri internum, leading to flow of the lochia and consequent diminution of temperature. Rapid improvement was usually effected, followed by complete recovery in about five or six days. The dose given was ten minims every three hours, the dose being doubled or trebled if necessary according to the indications of the pulse. In seven of the cases the uterine douche was not used. The maximum amount of tincture of digitalis swallowed by any one patient was twelve fluid drachms and thirty minims in five days. Criticism was specially directed to the "fool's paradise" of the uterine douche in unskilful hands, a calamitous record of treatment which has led to the loss of countless lives.—Dr. DONALD, Dr. LLOYD ROBERTS, Dr. STOOKES, Dr. DAVIES, and Dr. GEMMELL took part in the discussion which followed, and Dr. WHITTLE replied.

LIVERPOOL MEDICAL INSTITUTION.

Successful Brain Localisation and Operation for Idiopathic Insanity.—Membranous Cast of Trachea and Bronchi.—Treatment of Dacryocystitis.—Treatment of Lateral Curvature of the Spine.

A MEETING of this society was held on Feb. 25th, Dr. RICHARD CATON, President, being in the chair.

Mr. STREET and Mr. DAMER HARRISSON related a case of Successful Brain Localisation and Operation for Idiopathic Insanity. The patient was a man, who for two years had hallucinations of hearing, without any previous head injury. He became depressed, was unable to sleep, and took to drink. The voices were those of friends far away, and they goaded him to destroy himself in order to avoid disgrace. He had constant headache on the left side. He took six grains of opium daily without procuring sleep. He had attempted to cut his throat. Mr. Damer Harrisson trephined, making a large opening over the centre for hearing and opened a serous cyst. The result was entire recovery, and the man is now at work.

Dr. P. DAVIDSON showed a Membranous Cast of the Bronchial Tubes with numerous branches. It had been coughed up by a child supposed to be suffering from diphtheria. Part of this examined microscopically was found to contain almost a pure cultivation of micrococci. No Löffler's bacillus was discovered. Dr. Davidson, however, considered the case undoubted diphtheria. There was membrane on the tonsils and in the respiratory tract. Tracheotomy had been performed for dyspnœa. Diphtheria antitoxin had been injected. The patient was shown still wearing a tracheotomy tube. Dr. Davidson remarked that in several of the most marked cases of diphtheria that he had seen no Löffler's bacillus had been found in the membrane examined.—Mr. BARK drew attention to the value of curetting the trachea and bronchi through the tracheotomy wound in cases of diphtheria where dyspnœa occurs after the operation.

Mr. HUGH E. JONES read a paper on the Treatment of Dacryocystitis. Of fifty consecutive cases of mucocele, blennorrhœa, and abscess of the lacrymal sac, thirty-seven had neither cicatricial stricture of the nasal duct nor obvious disease of the nose. The remaining thirteen were divided amongst various forms of organic stricture and of coarse nasal disease. The cause of the obstruction in the large majority of cases was engorgement of the erectile tissue around the duct and catarrhal swelling of the lining membrane. Later the obstruction was due in a large measure to over-distension of the sac. The objects to be kept in view during treatment were—(1) to avoid interference with, and to preserve as far as possible the physiological integrity of, the organ; (2) to render the whole tract aseptic and to restore the mucosa to a condition of health; and (3) to reduce reflex irritation of the lacrymal gland to a minimum. The prolonged use of probes (especially large ones) and styles (apart from direct injury) induced sclerosis of the tissues, made the canaliculus of no physiological use, and sometimes caused periosteal stricture of the duct. These means of treatment should be classed among *derniers ressorts*. Partial slitting of the canaliculus followed by antiseptic irrigation, as suggested ten years ago by Edgar Browne, was by far the best, most scientific, and most rapidly successful treatment. The fact encouraged him (Mr. Jones) to dispense with slitting the canaliculus in suitable cases, and he made instead an opening in the dome of the lacrymal sac above the tendo oculi. In incipient cases of obstruction injections of a solution of cocaine and pinol in paroleine, made with Anel's syringe through the undivided canaliculus, seemed the most rational, paroleine being very diffusible and cocaine reducing vascular engorgement.—Mr. BICKERTON said he would adopt the irrigation treatment in all cases where symptoms of obstruction of the nasal duct had existed for a comparatively short time. But he dissented from the following statements of Mr. Jones: (1) "that undoubted cicatricial periosteal and bony stricture was rare"; (2) that treatment "by large probes, Stilling's knife, and styles were *derniers ressorts*"; (3) that they should be classed with such extreme methods as excision of the lacrymal gland and obliteration of the lacrymal sac; (4) that "the assumption (in practice) that the prime cause of dacryocystitis is in nearly every case stricture (i.e., cicatricial stricture) of the nasal duct cannot be sustained"; and (5) that "the prolonged use of probes and styles in treatment induces sclerosis of the tissues and sometimes causes stricture of the nasal duct." The rest of the discussion on this subject was adjourned to the next meeting.

Mr. BANKS read a paper on Practical Experience in the Treatment of Lateral Curvature. He dealt with the early symptoms of lateral curvature of the spine, such as rotation of the vertebræ, projection of the transverse processes and prominences of the scapula and ilium; with the theories of the production of these; with the general points to be held in view during treatment; and, finally, with the details such as couches, seats, exercises, mechanical appliances to the body, correction of bad habits of posture, &c. The paper was illustrated by diagrams and specimens.—Mr. ROBERT JONES said that the causation of the curves was still obscure, despite the experiments of Judson, Bradford, and Lovett. Amongst early symptoms care should be taken to discriminate between the lateral deviation due to unilateral absorption in spinal caries and starting scoliosis. He strongly deprecated the use of shoulder straps and poroplastic jackets.—Mr. RUSHTON PARKER and Mr. A. MACLEOD ROSS also took part in the discussion.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens.

A PATHOLOGICAL meeting of this society was held on Feb 19th, Dr. BRAITHWAITE, Vice-President, being in the chair.

Dr. CHURTON showed a specimen of Sarcoma of the Kidney. The patient had been under observation eight years. There was no secondary growth elsewhere.

Dr. WARDROP GRIFFITH showed specimens of Changes in the Osseous System. Among these was one of Osteo-arthritis of the Spine, with thickening and ossification of the anterior common ligament of the bodies causing ankylosis of eight

Hosted by Google

vertebræ. At one point this splint-like mass was fractured and a false joint had developed.

Dr. WARDROP GRIFFITH and Mr. LITTLEWOOD showed an Intestine from a patient who died from empyema, but who was operated on two years ago for a foul-smelling abscess in the region of the cæcum. The point of interest was that the only evidence of any operation was a slight dimple in the peritoneum opposite the skin incision and some very slight extremely delicate adhesions around the appendix which did not present any evidence of disease beyond slight thinning of its mucous membrane at one point and in the peritoneum. Close to this was a small mass of cheesy-looking pus the size of a pea.

Dr. BASIL HALL showed a series of Casts of Deformities of the Feet. These included single and double club-foot, pes cavus and acquired talipes equinus, and calcaneus.

Dr. BRAITHWAITE showed some sections of Glandular and other forms of Fungosities of the Uterus.

Dr. BARRS showed the Viscera from a case in which the diagnosis lay between splenic anæmia and idiopathic anæmia.

Mr. C. J. WRIGHT showed some large Masses of Molar Tissue removed from the uterus on two occasions, four weeks after the birth of a full-term living child. The patient, who had had three confinements and was thirty-six years of age, had a natural labour, but the uterus still remained large, leading to the supposition that there was another fœtus. On the twenty-seventh day she was brought to Mr. Wright with a protrusion from the vagina the size of a cocoanut. Dense, offensive membranous masses which filled a pint basin were removed, and the next day under ether the uterus was emptied and cleansed. The patient made a rapid recovery. There had probably been a twin conception with one ovum blighted.

Dr. SELBY showed—(1) a Tuberculous Kidney which had become converted into a Fibrous Structure containing Embedded Calcareous Masses; and (2) a specimen of Double Calculous Pyo-nephrosis, the right kidney containing numerous calculi with a quantity of fœtid pus, and the left being converted into a loculated pyonephrosis containing about two pints of very foul pus.

Dr. HELLIER showed Shäffer's Gynæcological Plates and a Uterus removed by Vaginal Hysterectomy for Carcinoma, the patient eventually recovering.

Mr. LITTLEWOOD showed Sixty Calculi removed by suprapubic operation from the bladder of a patient aged sixty-nine years.

Mr. SECKER WALKER showed the two halves of an Eyeball incorporated with a Spindle-celled Leuco-sarcoma which filled the orbit.

Mr. WALTER THOMPSON showed the Large Intestine of a patient who had died suddenly twenty-four hours after the administration of ether per rectum for an operation on the mouth which lasted forty minutes. Four ounces of ether were used. The mucous membrane was congested and almost all over was marked by extravasations of blood.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

Exhibition of Lantern Slides.—The Applied Anatomy of the Rectum.—Organic Sulphates of the Urine.

A MEETING of this Section was held on Feb. 5th, Dr. JOHNSON SYMINGTON, the President, being in the chair.

Dr. A. FRANCIS DIXON exhibited a number of lantern slides illustrating Early Human Embryos. The first slides illustrated an unopened chorionic sac, measuring 8 mm. by 7 mm. by 3 mm., the probable age of which was estimated at fourteen days. The flattening of the sac was assumed to be due in great part to shrinking of the decidua by which it was surrounded when first obtained by Dr. Murphy. The greater part of the sac was covered all over by short, stout, slightly branched villi. Over one pole, however, there was a bare area of small size. The presence of this bare area and the size of the sac would fix the age of the ovum at fourteen days. This determination agreed sufficiently well with the history of the case from which it was obtained. The second series of slides illustrated the external anatomy of two embryos of from twenty-two to twenty-three days. In one the amnion and yelk sac had been removed, while the other was photographed through the amnion, and the yelk sac was in position. Finally, three photographs were shown of an embryo of from thirty-three to thirty-four days. In this last embryo the photographs displayed not only the external markings on the embryo itself, but also gave a good view of the allantoic and vitelline arteries.—The PRESIDENT asked Dr. Dixon what preservative he used for the embryos. He himself had found corrosive sublimate the most satisfactory.—Dr. BIRMINGHAM inquired as to the method in which the photographs were taken.—Dr. DIXON, in reply, said he had always used methylated spirit for preserving his human embryos. Nitric acid was best for preserving fowl embryos. In photographing, the specimens were placed in glass cells with dark bottoms, the cells were completely filled with spirit and the cover slid on, so as to exclude all air bubbles. Special care had to be taken with the lighting.

Dr. EDWARD H. TAYLOR made a communication upon the Applied Anatomy of the Rectum, which he illustrated by lantern slides of frozen sections and of dissections specially prepared to illustrate the structures met with in perineal and sacral excision of the rectum. Having demonstrated the principal relations of the rectum in both sexes he referred to its sphincteric apparatus, which is constituted by the two sphincters and the levatores ani muscles. The latter were shown and the *rôle* played by them as rectal sphincters pointed out. It was evident, from the antero-posterior direction taken by the fibres of these muscles by the sides of the rectum, that in contracting they compressed the bowel laterally. In proof of this statement Dr. Taylor mentioned that if the finger were introduced into the rectum in the living subject both the extent and the tonicity of the anal canal (sphincteric zone) could be well determined. It was possible to appreciate a deep and a superficial contracting zone. The latter was certainly due to the external sphincter, whereas the former was evidently caused by the levatores ani, the contractions of which were both voluntary and sudden, thus differing from the internal sphincter, which contracted slowly and independently of the will. In perineal excision of the rectum Dr. Taylor laid stress upon the importance of always making an attempt, even when the sphincteric zone of the rectum had to be removed, to re-construct a modified sphincteric apparatus, and showed how this might be done by carefully preserving as much of the levatores ani muscles as possible and afterwards connecting them with the healthy end of the gut by a series of deep sutures. The applied anatomy of sacral excision was then considered and illustrated by photographs of dissections.—The PRESIDENT was glad to see that Dr. Taylor had emphasised the distinction between two parts of the rectum—the sphincteric and the supra-sphincteric areas; he (the President) would go further, for he held that they were functionally and anatomically distinct—the former was capable of acting as a reservoir, while the latter, which he had called the anal canal, was not.—Dr. BIRMINGHAM expressed the opinion that the internal sphincter was not a real functional sphincter of the anus at all. Its use was to force the fæces through the canal during defecation. The levatores ani, he believed, were the chief sphincter.—Dr. PURSER was inclined to agree with Dr. Birmingham's view of the nature of the internal sphincter.

Dr. COFFEY read a note on Organic Sulphates of the Urine.

TAUNTON AND SOMERSET HOSPITAL.—The annual meeting of the governors of the Taunton and Somerset Hospital was held on Feb. 11th, under the chairmanship of Dr. E. Liddon, J.P., the retiring president. The report of the committee congratulated the subscribers upon the continued and increasing usefulness of the hospital and the nursing institute. There was a deficit on the general account of £660, and a surplus of £243 on the nursing institute account. The committee suggested that this year, in which would be celebrated the sixty years' reign of the Queen, might be made the occasion of some special effort to improve the financial position of the hospital and enlarge the scope of its work, and it was decided to ask the Lord-Lieutenant of the county, the Earl of Cork, to call a public county meeting with this object in view. The Hon E. W. B. Portman was elected president for the ensuing year.

Reviews and Notices of Books.

The Diagnosis and Treatment of Diseases of the Rectum. By WILLIAM ALLINGHAM, F.R.C.S.Eng., ex-member of the Council of the Royal College of Surgeons of England; and HERBERT W. ALLINGHAM, F.R.C.S.Eng., Surgeon to the Great Northern Central Hospital and Assistant Surgeon to St George's Hospital. Sixth Edition. 1896. Baillière, Tindall, and Cox. Pp. xvi. and 485. Price London: 12*s.* 6*d.*

THE most striking characteristic of this volume is its eminently practical aim. Very little space is allotted to the discussion of abstruse questions of etiology and pathology, though these are by no means ignored, but the diagnosis and the treatment of the various morbid conditions are dealt with very fully and receive the greatest share of attention.

As a practical treatise on the diseases of the rectum we consider the book to be deserving of sincere praise, yet there are several points on which we cannot fully agree with the views put forward by the authors. In the description of the varieties of internal hæmorrhoids we find one variety called the "arterial hæmorrhoid." It is true that it is by no means uncommon to find a fairly large artery in the centre of an internal pile, but it is never found that a hæmorrhoid consists entirely or even in great part of arterial vessels, for such hæmorrhoids do not exist. Those which are so named consist for the most part of dilated veins. We heartily endorse all that the authors say as to the undesirability of injecting carbolic acid for the cure of hæmorrhoids, and, in fact, the method is but little practised at the present day in this country, but we must express our dissent from the condemnation which they also give to the treatment of hæmorrhoids by "crushing." When carefully employed excellent results are obtained, especially when combined with the use of the actual cautery, for by this treatment no hæmorrhage occurs, and this was the only drawback to Pollock's method. We acknowledge that ligature, the operation which the authors of this book chiefly favour, gives very satisfactory results, but this fact should not be allowed to discredit unduly other operative procedures.

As to Whitehead's operation, we are told that it is "one of the worst operations for piles," and yet with curious inconsistency the authors go on to say that for those who persist in employing this method an instrument devised by themselves is of "great assistance in simplifying this operation and in remedying some of its defects." We must protest against the statement that the operation is "difficult to perform," and certainly in suitable cases its results are unsurpassed. The book has reached a sixth edition, a distinction which it well deserves, for it supplies a very readable treatise on the diseases of the rectum.

The Practice of Midwifery: A Guide for Practitioners and Students. By D. LLOYD ROBERTS, M.D. St. And., F.R.S. Edin., F.R.C.P. Lond., Physician to St. Mary's Hospital for Women and Children, Manchester, Consulting Obstetric Physician to the Manchester Royal Infirmary, &c. Fourth Edition. London: J. & A. Churchill. 1896. Price 10*s.* 6*d.*

THE new edition of Dr. Lloyd Roberts's favourite little text-book has been considerably enlarged, containing nearly 200 pages more than its immediate predecessor, and the number of illustrations has also been considerably increased. The work has been revised, and many of the chapters have been re-written. We are glad to observe that the subject of antiseptics in midwifery has been given a chapter to itself, for although the author says "there is no need to insist upon the necessity for surgical cleanliness on the part of *medical attendants* and *nurses*," he implies that it is, in fact, of the greatest importance to take every possible care to obtain it, and proceeds to give a clear account of what must be done with this object in view. We observe that, while mentioning a solution of perchloride in glycerine as a lubricant for the examining finger, he rather prefers sapo mollis B.P., with 5 per cent. carbolic, or 1 per cent. lysol—as these "facilitate subsequent washing"—for the purpose in question.

There are a few points here and there on which the information in the text is a little open to criticism; for instance, in describing ballottement the author says: "The point of one finger is passed to the cervix uteri and a sudden impulse made in an upward direction," &c., whereas of course the right position for the finger in order to obtain this sign is in the anterior fornix. Again, in speaking of mento-posterior positions of the face, it is stated that "mento-posterior cases are dangerous because of the stretching and pressure on the bloodvessels of the extended neck. It is advisable to relieve this as soon as possible, and forceps are to be used early if rectification does not occur naturally or by means of the method indicated above"; but it is not impressed on the student, as we think it should be, that delivery with the chin posterior is impossible in the large majority of cases, and that, unless the chin can be made to rotate forwards, craniotomy will be required. We think also that at the present day the description of transfusion of blood for hæmorrhage might well have been omitted, since this operation has been very generally replaced by the intravenous injection of saline fluid. At the same time these are minor defects and do not materially detract from the general excellence of the work. We have no doubt it will be found by the present generation of students to be a useful exposition of the subject—concise and generally reliable.

A Manual of Clinical Diagnosis by Means of Microscopic and Chemical Methods. By CHARLES E. SIMON, M.D. London: Henry Kimpton. 1896. Price 16*s.*

THERE is little need in the present day to dwell on the value and importance of the assistance given to clinical diagnosis, and therefore to treatment, by a thorough microscopical and chemical examination of the products of disease or of the blood and the various excretions. So important is it that within the past decade many a work has been published devoted solely to this one branch of clinical investigation, and there is no medical school where instruction upon it of a systematic kind is not to some extent imparted. Nevertheless, this necessary extension of the field of observation is in itself so wide and comprehensive that it becomes more and more difficult for the practitioner to follow. It needs a special department and a staff of highly trained experts to carry it out to the full; and it is this class of work which is being so well undertaken in this country by the Clinical Research Association. The author of the volume before us has enjoyed at the Johns Hopkins Hospital, Baltimore, ample opportunities for the study of the subject, and his treatise is in every respect excellent. Covering practically the same ground as the well-known work of Professor von Jaksch, the book contains in some sections even more information than does that volume. It is evident, too, that the author has himself largely confirmed the statements which he makes, and occasionally he feels bound to differ from the somewhat too dogmatic teaching that has dominated parts of the subject. We have, after a careful review of the contents of the book, no hesitation in commending it as one of the best and most compendious manuals for the clinical laboratory that has yet appeared. The subject-matter is arranged on a very systematic plan, the text is not burdened by references to literature, and the descriptions of apparatus as well as the instructions for the performance of tests are

Hosted by Google

clear and concise. Perhaps the best section is that devoted to the urine, occupying about one-half of the volume, but the sections on the blood and on the gastric juice and gastric contents are little, if at all, inferior in scope and fulness. In his preface Dr. Simon pleads for a more thorough recognition of these studies in places of instruction, and urges the younger members of the profession to pursue them with diligence. As he says, "It is inconceivable that a physician can rationally diagnose and treat diseases of the stomach, intestines, kidneys and liver, &c., without laboratory facilities." Whether his suggestion that physicians might usefully employ a laboratory assistant to enable them to carry out this duty will ever be realised, time with its advance of knowledge can alone show.

The Fall of the Congo Arabs. By SIDNEY LANGFORD HINDE, Medical Officer of the Interior, British East Africa, late Captain, Congo Free State Forces, &c. London: Methuen and Co. 1897. Price 12*s.* 6*d.*

This is an interesting book about an interesting and, to the average reader, little known country. Mr. Hinde served for some three years as medical officer to the Congo Free State forces during the campaign undertaken by the Belgians against the vassals and successors of Tippu Tib. The commandant was Baron Dhanis. All records of bush-fighting have a great resemblance the one to the other, and Mr. Hinde's are no exception to this rule, but he gives us a number of facts about the various tribes he encountered of whom perhaps the most remarkable are the Batwa, "the little people of the forest." These pygmies live in the dense forest of the Congo basin, are under four feet in height, and are armed with bows and arrows. Though feeble weapons to look at, they are extremely deadly, firstly because they are poisoned, and secondly because their owners can send three or four arrows so rapidly in succession that the last leaves the string before the first reaches its mark. The nature of the poison is unknown, and Mr. Hinde does not venture upon any speculations as to what it may be. "A man will die in from three to ten minutes after having been scratched. An elephant ..... scratched on the haunch by a poisoned spear fell down dead before going a hundred yards." Most of the tribes in the Congo basin are cannibals, and Mr. Hinde's followers after a fight always ate up the killed. The author's experiences with small-pox are worthy of notice, and we commend them to those ignorant fanatics who delight in risking the spread of disease in Leicester and Gloucester. "Our Hauswas were, with one exception, all vaccinated, and this man was the only one in the company who caught small-pox, and he died of it. In the Elmina company there were only two men unvaccinated, both of whom got small-pox and one of whom died of it. Of our Lower Congo porters very few had had small-pox, and only some half-dozen had been vaccinated. Among this body of 200 men rather over two-thirds took small-pox, and there were 65 deaths among them." Many tribes inoculate with small-pox, not having any vaccine; and unfortunately all the vaccine sent out to Mr. Hinde proved apparently inert. The book, though full of adventure and out-of-the-way matter generally, is very simply and modestly written.

JOURNALS AND REVIEWS.

The British Journal of Dermatology for January and February contains a Case of Myoma Multiplex of the Skin, by H. Radcliffe Crocker, with chromo-lithograph in the January number and microscope drawings in the February number; a comprehensive account and abstracts of all the published cases of this rare disease are appended to the history of the case. Malignant Syphilis is ably discussed by A. Neisser of Breslau. L. Wickham in a letter from Paris gives some interesting notes on Lichen Planus of the Mouth without Skin Eruption, which appears to be less known in France than in England; on Acanthosis Nigricans; and on Hereditary Syphilis of the Bones and Teeth. Reports of the Dermatological Societies and the usual abstracts from foreign sources conclude the January number. In the February number, besides the conclusion of the article on myoma alluded to, there is the record of some careful work by Justus of Budapest on the Alterations of the Blood Produced by Syphilis, in which he shows that the amount of hæmoglobin is greatly reduced in the secondary period without treatment, while with large doses of mercury there is a rapid and considerable further diminution which is soon recovered. This sudden diminution after the administration of mercury only happens in syphilitics and no longer occurs when the syphilis remits or is cured. W. T. Freeman gives a note on skin irritation caused by handling hyacinth bulbs, and H. Skinner furnishes a useful pharmaceutical criticism on some new remedies and formulæ. It will be seen, therefore, that the articles are of scientific, clinical, and practical interest.

Archiv für Dermatologie und Syphilis. Vol. XXXVIII. 1897. Parts I. and II.—This old-established periodical keeps up its reputation. Part I. contains an elaborate illustrated article by Max Joseph on the Anatomy of Lichen Ruber Planus, Acuminatus and Verrucosus. A case of Lichen Planus is reported which was treated at the Breslau Hospital by subcutaneous injections of arsenic which produced arsenical pigmentation, keratosis of palms and soles, and peripheral neuritis, though the author, Max Dreysel, was inclined to consider alcohol as the cause of the last symptom. C. Bruhns, of Bern, relates his investigations on the much vexed question of the etiology of trichorrhexis nodosa, a disease of the hair which appears to be common in Bern. While his own experiments were negative as far as adducing proof of the bacteriological origin of the disease is concerned he concludes that therefore it cannot be proved to be a bacterial disease, although there are some facts in favour of it. Kopp gives a short account of a case of Multiple Angiomata in a young man. They seem to have been numerous stellate capillary striæ, of which cases have been described and figured in this country. Finally, J. Schütz recommends that Lupus Erythematosus should be treated by repeatedly painting with a diluted Fowler's solution 1 to 5 or 8, until some redness and swelling is produced, when the part is soothed until the inflammation has subsided and then the painting is resumed. In Part II. the original articles are:—1. A. Kozerski describes a Case of Actinomycosis of the Skin treated with success with large doses of iodide of potassium. Photographic illustrations before and after treatment are given. Ten grammes of iodide a day were reached. He states that suppuration may be produced by the actinomycosis fungus alone without the intervention of pus cocci. Some writers recommend washing out the sinuses with the iodide solution. 2. K. Herxheimer describes three cases of what he designates as Impetigo Contagiosa Vegetans, and in connexion with their histology he discusses the pathology of the protoplasm of epithelial cells. 3. L. Wallsch gives a further communication on the Pathology of the Hyphomycoses, taking the anatomy of pityriasis versicolor as his special theme. 4. M. Hintner adds yet another case of Multiple Skin Gangrene in an anæmic, strongly nervous girl, aged twenty-one years, but rejects the theory of its being self-induced. 5. E. Spiegler contributes Histological Studies on Eczema Marginatum, illustrated with three plates. He finds the fungus exclusively in papules formed by the altered horny layer and that it never penetrates into the rete. 6. Löblowitz advocates the use of airol, an iodine compound with dermatol, in dermatological practice, and

Hosted by Google

thinks that it may even supersede iodoform. Both numbers conclude with the usual reports of societies and copious extracts from dermatological literature.

Chirurgia. Vol. I., No. 1. January, 1897. Edited by Professor DIAKONOF. (Monthly, 8 roubles per annum.)—This is the first number of a new Russian journal, published under the editorship of the Extraordinary Professor of Operative Surgery in the University of Moscow. As its name implies it is devoted entirely to surgery. Nearly half the present number is taken up by Dr. Pomerantzef's article on Brom-ethyl as an Anæsthetic. The subject is discussed mainly from its chemical aspect; the writer regards brom-ethyl as a safe anæsthetic, suitable for country practice, as it can be kept for a long time without decomposing, while the yellow discoloration shows at once if decomposition has set in. The chemical tests of its purity are also very simple and easily applied. Dr. Sventzitzki discusses the technique of Trephining. Dr. Ikavitz reports a case of Wound of the Liver through the Thorax followed by recovery; and Dr. Varnek describes two successful cases of treating Tuberculous Peritonitis by operation. An article on Extra-uterine Pregnancy by Dr. Bobrof completes the original communications. The remainder of the number contains brief abstracts of a group of twenty-six articles in different languages on Diseases and Injuries of the Head, a series of reviews of current surgical literature by the editor, and short notes and news. The journal is well printed on good paper. The editor's address is Moscow, Tverskaia, No. 69.

Among the monthly publications of the Religious Tract Society the *Sunday at Home* has a brief article on Stangate Creek, the Medway Quarantine Station. At one time it was the custom to bury those dying on board a quarantined vessel in the adjacent marshes, and there still exists one solitary gravestone which serves to mark, not only the burial place of many victims of fever and plague, but also the resting place "of one of the many heroes of the medical profession who, in seeking to save life, have lost their own." This is the grave of Sidney Herbert, a surgeon of the Royal Navy, who succumbed to fever while attending to the sick on board H.M.S. *Eclair*. The vessel was placed in quarantine on her return home from the West Indies in 1845.—The *Leisure Hour* contains several articles of interest, among them a sketch of Mr. Ruskin's Social Experiment, the St. George's Cottages, Barmouth.—The *Girl's Own Paper* and *Sunday Hours* are interesting as usual.

St. Mary's Hospital Gazette.—The February issue contains an editorial reply to our question asking whether it would not "be possible for the new medical officer [the casualty physician] while making his selection of suitable cases from a medical point of view to give an eye to each case with regard to the worthiness on the part of the patient to receive free treatment." Says the editor: "To the initiated it is clear that the strictly professional duties of the casualty physician will be more than sufficient to occupy his attention without entering into the social conditions of the patients." We can only say that if "to the initiated it is clear that the strictly professional duties of the casualty physician will be *more* than sufficient to occupy his attention," he would be far better employed in the occupation suggested by us. If his duties will be more than sufficient to occupy his attention, it was a farce to make the appointment.

Guy's Hospital Gazette.—The first part of a Clinical Lecture by Dr. Newton Pitt in the current number will be read with interest, as the number of cases admitted into the medical wards has very greatly increased of recent years. "R. O. M." concludes his Notes from a Holiday in Persia with a hint to patients suffering from nervous debility or from eating or drinking too much. "I could most highly recommend," he says, "the ride from the Caspian Sea to the Persian Gulf as a variation on the traditional sea voyage and baths."

The March number of the *Practitioner* contains some wholesome editorial remarks upon Hospital Reform, one of which is as follows: "I am convinced that until some penalty is attached to the abuse of medical charities things will remain pretty much as they are." Mr. Morris suggests that any deliberate abuse might be dealt with as fraud, or, at any rate, as begging. Coming to the more purely professional papers Sir Dyce Duckworth has an interesting communication upon Cirrhosis of the Liver, laying stress upon the fact that it is not a merely local disease, but only a local manifestation of a very general disease. He also points out that in the later stages great benefit to the patient, if not to the complaint, arises from the giving of a little alcohol. Mr. Quarry Silcock writes upon Empyema of the Frontal Sinus, and Dr. Archibald Donald upon Phantom Tumour, which, he says, is by no means always hysterical, and quotes an interesting case where the tumour was a reflex symptom produced by pelvic peritonitis. Dr. Greig Smith brings forward facts to prove that Robert Houston did not perform an ovariotomy in the celebrated case of Margaret Millar, but only incised and drained an ovarian cyst.

THE INTERNATIONAL SANITARY CONFERENCE.

THERE is not very much to be chronicled this week in regard to the International Sanitary Conference at Venice, but a good deal of work has nevertheless been done and things are progressing favourably; the discussions that have taken place have served to clear the atmosphere, as it were, and their general trend has been of a business-like character and in a practical direction. The technical committees have done much in formulating their reports. The announcement of the Hon. M. Herbert at a general sitting of the Conference that the Indian Government had entirely prohibited this year's pilgrimage was received with general applause. We are mainly indebted to the excellent accounts which have appeared in the *Times* for our facts regarding the Conference. Surgeon-Major-General Cleghorn's description, too, of all that has been or was being done at Bombay was apparently regarded as satisfactory, although, as might have been anticipated, some of his deductions and views in regard to the nature of the plague and its intimate connexion with and dependence upon local conditions rather than upon its purely contagious properties did not carry conviction to all. He said that since the outbreak in Bombay about 300,000 people had left the city and that the disease had only been carried to and effected any lodgement in one other place (Karachi), and that the panic prevailing in Southern Europe was to be deprecated. The delegates of the various Powers followed with announcements of the action taken or proposed by their various Governments. Russia has prohibited all, even Christian, pilgrimages within her dominions. Persia announced the suppression of Shiite visits to Mesopotamia and described the composition of the Sanitary Council at Teheran. Turkey, holding that pilgrimage was one of the cardinal points of the Mohammedan faith, declared that it could not be prohibited. No decision has apparently yet been arrived at by Turkey in regard to the ratification of the Paris Convention.

THE CANCER HOSPITAL (FREE), BROMPTON, LONDON, S.W.—The annual meeting of governors was held on Wednesday, Feb. 24th, Sir George Samuel Measom being in the chair. The report showed that during the past year 2345 new patients were received, 829 as in-patients and 1516 as out-patients, whilst the total number of attendances of out-patients was 13,786, these figures being in excess of any previous year. The report and balance-sheet were adopted and the usual vote of thanks accorded, after which the proceedings terminated.

THE LANCET.

LONDON: SATURDAY, MARCH 6, 1897.

IT is undeniable that the subject of the abuse of hospitals is coming to the very front of questions affecting the prosperity of these institutions. The response to the kind and wise appeal of the PRINCE OF WALES and the munificent gift of Sir BLUNDELL MAPLE are proofs, if any were wanting, that money enough will be forthcoming if the public can be satisfied that it is well used. It is, indeed, possible that more than enough money may be forthcoming—a possibility which only makes it the more proper to take precautions against such a sum being used in a way to swell the existing evils. We are persuaded that many who are working most cordially and actively for the success of the PRINCE OF WALES'S Hospital Fund for London are sincerely anxious that it shall do the greatest amount of good and the least amount of harm. But the ardent friends of hospitals are apt to fall into a completely one-sided view of schemes for the benefit of these institutions. It is on record, as Mr. LOCH has pointed out, that Sir SYDNEY WATERLOW, in the early days of the Hospital Sunday Fund, was careful to point out that hospitals were not meant to exempt the working classes from making their own provision for attendance on themselves and families in the ordinary sicknesses of life—a provision which many of them make in medical clubs, or friendly societies, or, best of all, by application to a local practitioner. But in later years Sir SYDNEY WATERLOW has been increasingly reluctant to see the growing abuse of hospitals, which to everybody else is so apparent, and to use the great power of the Council of the Hospital Sunday Fund for its friendly correction. Mr. BURDETT is a still more striking example of the danger of a one-sided view of the hospital question. He has represented the evils of the out-patient system to be such as called almost for its abolition—at least, for a time. Yet when an opportunity offered in the Council of the Hospital Sunday Fund for helping the friends of reform he came to the conclusion that the Council was "only a collecting body, and the proper persons to deal with hospital abuse are the members of the medical profession"! Can anything be said more ikely to belittle the Council of the Hospital Sunday Fund or the religious bodies which so generously contribute to it as to represent them as mere collectors, without intelligence or responsibility for securing the right use of what they collect? The public prominence which is now being given in the medical and the lay press to the facts of hospital abuse will soon convince Mr. BURDETT that mere collectors are not so numerous or so blind a species as he seems to think; but that sooner or later the facts will have to be faced and a remedy for abuses provided if subscriptions are not to fall off. And laymen who represent hospitals and administer the funds of the public subscribed for this purpose must take their share in devising remedies.

Still, the profession has an enormous responsibility in this matter. Its leaders work the hospitals. Their skill and their opinion, to be had gratis in the hospitals, and that almost without let or question, make the attraction of hospitals and make it more and more irresistible. This attraction has come to be so great as to draw practically a fourth part of the inhabitants of the wealthiest city in the world, including—it has been demonstrated over and over again—a proportion of really wealthy and comfortable people, and, of course, a much larger proportion of well-paid workpeople. There is nothing else like it in any other department of life. Huge establishments for supplying all comers with clothes or food of the best on gratuitous terms would be scouted as demoralising to the applicants and unfair to subscribers, who meant only to help those who cannot help themselves. But in the matter of medicine pauperism is cultivated on a large scale by the laxness of hospital administration. It is excused on the score of the exigencies of the medical schools, though a distinguished surgical teacher of a great school has said that there are four times as many applicants as are needed for purposes of medical education. It seems the cruellest inconsistency in the world, on the one hand, to draw students by the thousand, and, on the other hand, to encourage the competitive action of hospitals by attracting the classes to which the students as young practitioners are to look for honest and self-respecting patients. Yet this is the demonstrated working of the out-patient system as at present administered, and in the last result it is upheld by the medical staffs of hospitals, as many of them are now beginning to see. It is a matter of urgent importance that it should be made clear to all members of medical hospital staffs that in the promiscuous services of the unregulated out-patient department they are encouraging a system which tends to dry up the springs of charity on the one hand and of providence on the other, and which saps the foundations of medical practice in all but the wealthier sections of society.

We are satisfied that this action of hospital physicians and surgeons is unintentional. They do not realise that they are unconsciously doing all this harm in work which superficially considered has a certain air of kindness and humanity. How can this impression be corrected? There is only one way, and that is by friendly discussion of the subject within the profession itself. Let there be no strife over the discussion. A conference should be organised by the coolest heads of the profession for the purposes of such a discussion, and the object of such a conference should be the union of the profession on this subject. If we are to be divided into consultants and non-consultants, if every man is to have his own remedy and reject every compromise, things had better remain as they are. But that would be a confession of failure, meaning alike the degradation of hospitals to the level of cheap dispensaries and the degradation of private practice to the starving point. There are indications in high quarters that this question of hospital abuse will have recognition. If the profession is united we shall succeed. If it is not we shall fail, and we shall deserve to fail. But one thing is certain, that the medical

Hosted by Google

staffs of the hospitals have the power to save hospitals and the profession by firm and united action. The present occasion is apt for such action, and we would earnestly impress upon those members of the profession concerned the absolute necessity of seeing that such an opportunity shall not be allowed to slip from their grasp.

IN a leading article in THE LANCET of Sept. 26th, 1896, we commented on the action of the Aberdeen students in getting rid of a professor who, while full of ability and erudition, had not the art of interesting or instructing them. First overt protest, then silent abstention from the class-room, was their plan of campaign. And it was successful. The University authorities, sitting in conclave on the situation, found the students so far justified that they requested the professor to retire on half the proceeds of the chair, and appointed a successor who, though not superior in natural or acquired ability, had the power of arousing and maintaining interest in the business of the class.

How differently they manage such matters abroad! From causes more or less cognate to that which impelled the Aberdeen students to action, the University of Athens, for instance, has had to be closed, the students holding the building in defiance of the military; while at Bologna, "the mother of universities," Senatus and students have been at open war, again requiring the intervention of armed troops. Bordeaux, too, has been recently the scene of similar collision, though on a minor scale, and Austria-Hungary and Russia have quite lately been furnishing object-lessons of a like deplorable kind. It would seem, in fact, as if only the Teutonic civilisation in general and its English-speaking branch in particular were capable of respecting and practically illustrating the exalted purpose for which universities are organised and maintained. Rare in Germany, academic indiscipline proceeding to violence is rarer still in the English-speaking world; and one result of this moral and social superiority is the undoubted fact that the scientific output of their schools is in quality and quantity greater than that of the whole outside world. There is one condition prevailing in Great Britain and denied to the nations of Southern Europe which may serve to explain the contrast between their academic records. In these islands there is pre-eminently the "settled government" which is of itself a factor in the maintenance of order and respect for authority. Greece and Italy, on the other hand, having thrown off within the century the foreign yoke which kept them down, have not yet thrown off the traditions inseparable from that ordeal. In both countries the elderly and middle-aged generation have passed their youth in an atmosphere of revolution. Their stirring, often noble, experience is still fresh in the minds of their sons, and between the two, the old and the young, the incidents of political upheaval and rehabilitation are fresh enough to mould and colour their attitude and thought towards the existing order. They are quick to perceive and quick to resent aught that savours of "authority" or "tyranny," and the consequence is seen, as successive Ministers of Public Instruction can too painfully attest, in the difficulty of exercising discipline or maintaining order in the universities of either country. If the Minister relies on the prestige of office or Cabinet rank he is reminded in the Chamber of Deputies that the students have their representatives there also—representatives drawn from the generation of their fathers—who began life in "the revolution." Our Rome Correspondent has recently commented on the opening of the winter session of the "Sapienza" and the collision between the Minister of Public Instruction and the students, provoked by the inflammatory address of the Professor of Moral Philosophy. The latter functionary had in consequence to receive a pointed reprimand, and the indignity thus inflicted on a rhetorical idol has been resented by the students ever since. The "solidarity" subsisting between all undergraduates throughout the kingdom explains the zeal with which the grievance of the Roman students has been taken up by their fellows in Naples, Palermo, Turin, and principally in Bologna, where the Minister, Signor GIANTURCO, was subjected to indignities which evoked the interference of the Senatus and the deplorable scenes of violence reported in the public press. His Excellency was on a State visit, prompted by the desire to do something for a vigorous, yet all too meagrely equipped, school—to furnish, *inter alia*, improved laboratories, cliniques, and other imperative conditions of academic efficiency. But this loyal purpose did not protect him from insults and violence on the part of the "socialist" students, whose ill-inspired conduct aroused, it is fair to say, a counter-demonstration on the part of their "monarchical" fellows. Between the two, however, in spite of professorial intervention, arose the collisions which brought in the military. The leading organ of the Italian Government, the *Opinione*, lately declared that it saw but one remedy for the recurrence of these tumults—the exclusion of "sectarian politics" from the universities. This, however, must be a work of time. The "premature publicist" is too rank, as well as too recent, a growth in Young Italy to be easily eradicated. The hour for that, as for other consummations, will not come until the great D'AZEGLIO'S aspiration be fulfilled: "Having made Italy, we have now to make Italians."

ALTHOUGH there is no prospect of the Food and Drugs Act being dealt with this session, the Bill providing for its consolidation and amendment has been prepared and was ordered by the House of Commons to be printed on Jan. 27th, 1897. We received a copy of this Bill last week, and we may say at once that it is a clear and very comprehensive measure and practically in complete accord with the recommendations of the recent Select Committee. We doubt, however, whether in its present form its sponsors will secure for it a calm and steady passage through the Houses of Parliament. Its very comprehensiveness will invite, if we are not mistaken, considerable contention. The object of the Bill is primarily to ensure the purity and quality of food and drugs sold to the public, but it must not be forgotten that it must very decidedly affect the traders and the trade of this country, and the interests of the traders must be safeguarded—in short, the Bill must be fair both to the purchaser and to the seller. On the face of it, while

Hosted by Google

the new Act is undoubtedly a somewhat drastic proposal, yet no one can honestly say that what are described in its provisions as offences are wrongly or unjustly so described. In our opinion it is an offence in any case for a person to sell to the prejudice of the purchaser any article of food, or drug, or clothing, or what not, which is not of the nature, substance, and quality of the article demanded by such purchaser. The public only want educating as to what they are entitled to ask for, and if that article is not supplied in accordance with this demand, an offence, we maintain, is committed.

There is little doubt that the new Act, if it come into force, will put an end to much of the farcical procedure in the police-courts, cases of which during the last decade have occurred with irritating frequency. The definition of food according to the present Act has opened the way of escape to many an offender. The addition of alum to baking powder, for example, was permissible, but not to bread or flour. The term "food" is now to include every article "used for food or drink by man, other than drugs or water," and, moreover, "any article intended to enter into or be used in the preparation of human food and flavouring matters and condiments." The definition of the term drug is also widened, and is now to mean any substance, vegetable, animal, or mineral, used in the composition or preparation of medicines, whether for external or internal use. The penalties suggested are more severe in regard to repeated offences. Thus, for a first offence the person charged is liable to a penalty not exceeding £20, for a second offence not less than £5 and not exceeding £50, and for a third or subsequent offence to not less than £20 and not exceeding £100, or, at the discretion of the justices, to imprisonment, with or without hard labour, for a period not exceeding three calendar months. An interesting return to the wholesome methods of punishment of our forefathers is clearly suggested in Section 4, where, in the event of a convicted person repeating the offence, a court may order a notice of the facts to be affixed for a period not exceeding twenty-one days to the premises occupied by him, or may also order them to be published by advertisement in such newspapers as the court may decide, the person so convicted being bound to pay the costs thus entailed. We think this an admirable proposal, and we hope it will commend itself to the majority, at any rate, of our legislators.

As to the administration of the Acts, the new proposals, as generally set forth, are, we think, commendable. The appointment of the analyst, his dismissal, and remuneration are at all times to be subject to the approval of the Local Government Board, and not to be left, as before, in the hands of local authorities or vestries. The number of samples to be taken is not to be less than one sample per annum for every 1000 inhabitants living within the area of such local authority. In the event of the local authority refusing or neglecting to do this the Local Government Board will appoint an officer to take the number of samples provided and thus to enforce this provision. The cost of the appointment and functions of this officer is to be defrayed by the negligent authority. This is as it should be, and is a provision which ought to do away entirely with the unpardonable apathy of the local authorities in this matter, of which we have so frequently complained in these columns for several years past. Lastly, immediately after the passing of this Act there is to be appointed a Board of Reference, and we are in entire concurrence with the choice of representatives that is suggested. The Board is to consist of the principal officer of the Laboratory at Somerset House, a person nominated by the Board of Agriculture, and persons to be nominated by the following bodies—two by the Society of Public Analysts, one by the General Medical Council, one by the Institute of Chemistry, one by the Pharmaceutical Society, one by the London Chamber of Commerce, and one by the Association of Chambers of Commerce, and if need be of three other persons, the appointment of all of whom is to be subject to the approval of the Local Government Board. The duty of this Board will be to deal with such matters as the qualification of analysts and inspectors and with questions concerning definitions of purity and the standards of composition of articles of food, as well as to decide upon the amount and kind of foreign substances to be allowed for the preservation or flavouring of preserved foods.

As a measure intended to raise the standard and quality of our daily articles of food we have not a word to say against the proposed Act; but, as must be admitted, it attempts to deal with a subject that presents considerable difficulties from the practical legislative point of view. With the growth of technical knowledge, the advance of technical skill, and the progress of scientific methods applied to manufacture and industrial pursuits, the task of successfully grappling with fraudulent practices in connexion with food-supply becomes involved in deeper difficulty day by day. To us it is interesting to reflect how enormous has been the development of this section of administration since the days of THE LANCET Analytical Commission, when the Founder of this Journal, the late Mr. WAKLEY, showed, by the startling results which were published in the earlier numbers of THE LANCET, the necessity of immediate legislative interference to check the pernicious practices which he proved to be going on in regard to the adulteration of food. At that time it was one man with a small band of assistants who brought to light the frauds committed upon the public; since then the Food and Drugs Act (1879) has been in force, which has required not only a large staff of analysts under the control of the Local Government Board to carry out its provisions, but in reality also a Society of Public Analysts to devise new methods for the detection of new frauds; and, again, in the new Bill of 1897 it is proposed to appoint a court of experts to modify any legislative procedure that is suggested as the outcome of the increased ingenuity of unscrupulous persons. The discussion of this Bill in the House of Commons will be watched with considerable interest; but for this we fear we must wait awhile.

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY. The February meeting was held at Lewisham Infirmary on the 27th ult., the President, Mr. Walter Burney, being in the chair. Dr. F. S. Toogood showed cases of Progressive Muscular Atrophy, Tuberculous Peritonitis, Abdominal Tumour, &c. The annual general meeting and dinner will be held at the Inns of Court Hotel on March 27th, at 6.30 P.M.

Annotations.

"Ne quid nimis."

THE EXECUTIVE COMMITTEE OF THE GENERAL MEDICAL COUNCIL.

THE proceedings of the Executive Committee, as representing the General Medical Council in the interval of sessions, have always a certain importance. On this occasion the number was short, owing to the vacancies created by the resignation of Mr. Wheelhouse and Sir Walter Foster not being filled till the day of meeting. As our readers know, Mr. Brudenell Carter and Dr. Glover were appointed but did not take their seats. Intimation of a change in the representation of the University of Aberdeen was received, Mr. R. W. Reid, M.D. Aberd., F.R.C.S. Eng., Professor of Anatomy, succeeding Dr. Angus Fraser, who was a very useful member of the Council. The committee had various communications on the subject of midwives. The Midwives Bill was referred to the General Medical Council by the Lords of the Privy Council. A letter was received from Mr. G. W. Duncan, secretary of the Midwives Bill Committee. Resolutions against the Bill were received by the committee from the Rochdale and District Medical Society. A communication from Dr. Rentoul, asking the Executive Committee to move the Government for certain returns as to the Poor-law employment of midwives, was read; also another from the same gentleman, suggesting the preparation by the Council of a new statistical report of the profession, and a third, regretting the small result of his exertions *re* the diplomas granted by the Rotunda and Coombe Hospitals. On the subject of the Midwives Bill the committee resolved to inform the Government that the Council will not meet till May, but has forwarded a copy of the resolutions of the Council on the Bill of 1895. The committee resolved that it was not within its province to ask the Government for the returns wished for by Dr. Rentoul. Such returns would certainly be interesting, and Dr. Rentoul might induce some member of the House of Commons to ask for them. Correspondence with the Registrar-General on the easy registration of deaths without medical certification was read. The answer of the Registrar-General cannot be regarded as satisfactory, though it confirms the view of the Council that registrars do not break the law in accepting statements by unregistered persons in lieu of medical certificates. Doubtless the President will carry out the wishes of the Council and seek an interview on this subject with the President of the Local Government Board. The Registrar-General has intimated his intention to put into his official list for 1897 the names of medical practitioners and dentists which have been removed from the registers. The subject of defective preliminary education was raised in communications from the Director-General of the Navy, which will be forwarded to the qualifying bodies affected. The Executive Committee through a sub-committee, will continue its attention to the subject of the disciplinary functions of the qualifying authorities. A communication from the Portsmouth Medical Union asked for an expression of the Council's opinion on the subject of "tendering" for appointments and underselling, but the Executive Committee resolved that the question raised does not fall within the statutory duties of the Council. A resolution passed by the Royal College of Surgeons in Ireland to the effect that the employment of unqualified assistants by medical men is most injurious and should be prohibited by the General Medical Council was received and entered on the minutes. In the dental part of the committee's business the chief matter was the correspondence between the Council and the Privy Council in regard to the case of Mr. A. P. Merrill, who claimed registration in the Dentists' Register both as a foreign dentist and a colonial dentist, and under Section 37 as a person articled as a dental pupil and whose articles expired before Jan. 1st, 1880. The Council had declined to register Mr. Merrill. He appealed to the Privy Council, and their lordships dismissed the appeal. The arguments will interest the dental profession, and are set forth at length in the correspondence published in the minutes.

THE AUER INCANDESCENT LIGHT AND ITS EFFECT UPON THE EYE.

SOME interesting discussion has taken place of late in regard to the effect upon the eye of the Auer incandescent light. The mantle of this incandescent system of lighting consists, as is now pretty generally known, of a network of the rare oxides (chiefly of thorium with a small proportion of cerium), which on being heated in the Bunsen flame emits a brilliant white light. As might be expected, this light is comparatively rich in the ultra-violet or chemically active rays that are identical with those in sunlight, and it has been urged that this richness in actinic rays may possibly be productive of injury to the sight. This argument appears to be based on measurements of wave lengths made by means of the spectroscope. The arc electric light, it is said, has similar effects, but of a more pronounced character. As yet there is no evidence of experience, as far as we know—and the Welsbach light has now been in use for several years—that the slightest injury to the optic mechanism where the system has been in use for domestic lighting has ever been produced; and unless a person deliberately stared at the naked light for some hours every day it would be surprising to learn that real injury could be referred to this cause. It is well known that the radiation of light downwards from the incandescent mantle is feeble, so that without a reflector or some reflecting surface at the top of the mantle, as in the ordinary way would be provided by a ceiling, much of the illuminating power would be lost. From the particular point of view under discussion this is, however, an advantage for the lighting of rooms, since reflected and not directly transmitted light is pleasanter and more agreeable to the eye, besides which in the phenomenon of reflection partial absorption takes place, so that the light becomes pleasantly diffused and of a healthy tone. In any case, if any apprehension should exist that the rays proceeding from an incandescing mantle are injurious because of their chemical activity—an activity which in sunlight gives life to the plant world—these rays could be readily and effectually filtered out by the simple expedient of surrounding the light with a tinted globe, such as red or orange, which need reduce but very little the originally high illuminating power. Even then the light is over 100 per cent. higher in illuminating value than the ordinary gas flame. Artificial light, of course, is most in request in the dark days of winter, and in that season, at the best of times, we receive but little more than eight hours' light from the sun, and then frequently it is largely filtered from its chemically active rays by the medium of a murky atmosphere. On the other hand, we enjoy in the summer just twice as much sunlight, which is then of greatly increased power, and the chemical activity of which is infinitely greater than could possibly be furnished by any known form of artificial light. Taking these simple facts into consideration we should almost expect to find in some form or other some manifestation or deterioration in the eyesight during the summer period, due to a largely increased exposure to the chemically active rays of solar light. We are not aware that any such manifestation has been observed. The argument that nature

Hosted by Google

intended us to rest from the effects of light as soon as the sun is below the horizon demands, if it can be reasonably applied at all, the rejection of all artificial means of lighting, since there can be no light of any kind of any aid to the eye whatever that can be without some chemical activity. Still less practicable does such a suggestion become when applied to the lands of the midnight sun and other places or to the arctic winter of several months' darkness. Clearly this theory could only be prompted by the consideration of the limited conditions of environment in the temperate zone. No men probably are exposed more freely and continuously to the chemically active rays of the sun than our sailors, yet their acuteness of vision and penetrative power of sight is a matter of admiration and wonder to everyone. Sunlight is by a thousand circumstances widely and uniformly diffused making it more acceptable to the eye, and during its journey to earth it undergoes an important modification, for in passing through the air it is deprived of some of the red rays, while the blue rays pass on—a circumstance which explains the azure character of the sky. In view of these facts, it is difficult to receive the theory with any seriousness that because there may be a certain proportion of ultra-violet rays in a given artificial light it is necessarily injurious. It would be a sorry thing if these same rays were for ever filtered out of the light of the sun by the medium of constant fog or cloud, as so often happens in the days of winter. Exposure to a purely elementary light, as red, yellow, or blue, does undoubtedly prove injurious either positively or negatively. The distress produced on working for some time, to quote one instance, in a red or yellow light, as in the dark room of the photographer, who employs one or other of these colours on account of their chemical inertness, is well known. Absence of sunlight is held to be synonymous with the absence of life, and the life-giving and invigorating qualities of solar light are largely, if not entirely, dependent upon the chemically active rays, and certain lines of scientific research have shown that without the great phenomenon of insolation going on day by day life would be unendurable and finally extinguished. White light, therefore, as afforded in its entirety by the sun, is a necessity of existence.

THE INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.

A MEETING of the English committee was held at 13, Harley-street, W., on Feb. 13th. The following members were present: Sir W. Mac Cormac (in the chair), Sir Dyce Duckworth, Mr. Langton, Dr. Lauder Brunton, Dr. Allchin, Mr. Henry Morris, Surgeon-Major-General Hooper, Dr. Champneys, Professor Thane, Dr. A. E. Garrod, and Mr. Makins. The secretary reported that fifty members, representing the various English universities, medical schools, and medical societies, had joined the committee, and several matters relating to the Congress were discussed. The preparations for the meeting at Moscow are now in an advanced state, the programme of work in several of the sections being nearly complete. Papers may, however, still be announced, the last date being June 1st next. The secretary-general, Professor W. K Roth, announces that the English Consul, Mr. Medhurst, is in communication with the principal members of the English colony residing in Moscow with a view to the entertaining of guests to the Congress; further, that ample hotel and lodging accommodation at reasonable charges will be forthcoming. It is hoped that the members of the Congress will be received at a Court reception by the Czar, and arrangements are being made for *fêtes* to be held at St. Petersburg after the termination of the meeting at Moscow. The cost of the railway journey to Moscow, returning by St. Petersburg, will be approximately as follows: A circular ticket from London, *viâ* Paris, Strasburg, Munich, Vienna, Oderburg, and Granica (frontier station for Moscow), and home *viâ* Eydtkuhnen (frontier station from St. Petersburg), Königsberg, Berlin, Cologne, Brussels, and Calais to London, available sixty days, first class, £17 5*s.*; second class, £12 4*s.* 6*d.*; 56 lb. of baggage free to Avricourt on the out journey and from Blandain on the home journey. For the remainder of the journey baggage must be paid for. The tickets for the Russian portion of the journey must be taken at the frontier stations, the cost being as follows:—Granica to Moscow, first class, 38 roubles 43 kr.; second class, 24 roubles 68 kr. Moscow to St. Petersburg, first class, 20 roubles 76 kr.; second class, 12 roubles 21 kr. St. Petersburg to Eydtkuhnen, first class, 17 roubles 90 kr.; second class, 10 roubles 74 kr. No return tickets are issued on the Russian railways. Taking the rouble at 2*s.* 3*d.* the approximate cost of the railway travelling will thus be: first class, £26; second class, £18; and it will be necessary to give eight days' notice to Messrs. Cook in order to obtain the circular tickets. The Secretary-General holds out some hope of the fares on the Russian lines being considerably reduced. All visitors will be required to be provided with passports. Forms of inscription as members of the Congress may be obtained from Mr. Makins, 47, Charles-street, Berkeley-square, W.

LEICESTER AGAIN.

LEICESTER, unlike the heroines of modern novels, has a past of which it may well be proud. But its present seems to be given up to the fostering of every kind of fad, and, like the gentleman whose politics were summed up in the simple words, "Agin the Government," Leicester seems to be always in opposition. Its views on vaccination are well known; consignments of "cheap tans" made, not of leather, but of "compo," come from there and figured in the Whitechapel County-court last year; and now it has started another fad. There is Mr. Pickering, who claims to cure fevers by giving baths, and the Leicester Board of Guardians have intimated to their medical officer, Mr. Bryan, that they would like the Pickering system tried in cases of fever brought to the workhouse infirmary. The house committee accordingly wrote to Mr Bryan asking the following questions: 1. Whether you have had an opportunity of ascertaining the methods employed by hydropathists, particularly those used by Mr. John Pickering, and the results obtained under such treatment? 2. Whether you are of opinion that the advantages claimed for this treatment are actually obtained; whether the course of the fever can be stopped, and the risk of complications and spread of infection prevented? 3. Whether you are prepared to adopt such treatment, either permanently or as an experiment? We are both pained and surprised to see the Leicester Board of Guardians suggesting a method of treatment "as an experiment" upon patients. However, we may safely leave them to the wrath of the Personal Rights Association and the Anti-vivisection Society, and we will pass on to Mr. Bryan's answer. He wrote—(1) that he was perfectly conversant, in common with the rest of the medical profession, with the use of baths, &c., in lowering temperatures, and that Mr. Pickering professed to destroy germs by a temperature of from 102° to 110° F.; (2) that he would not trifle with human lives; (3) that he had been medical officer to the workhouse for sixteen years and had never had a single death from scarlet fever; and, finally, that he would not allow any interference with his treatment, for which he alone was responsible. These obvious truths pained the house committee, and the clerk wrote back saying, among other matters, that "your statement that Mr. Pickering claims to destroy such fever germs as you refer to by means of baths is not correct."

Hosted by Google

Now some time last year Mr. Pickering was interviewed at Leicester, and we published portions of the interview in our issue of Jan. 2nd, 1897. There Mr. Pickering was reported as saying: "Extremes of temperature are destructive of germ or organic life in the blood. Cold water at 36° F., or hot water at 102° F., are conditions under which no fever can live." Supposing Mr. Pickering to have been rightly reported—and our quotation has never been contradicted—these words can only mean that Mr. Pickering considers that germs can be destroyed by a temperature of 36° F. or 102° F. The letter also asked if Mr. Bryan would watch some cases now being treated by Mr. Pickering. To the second letter Mr. Bryan replied that he would have nothing whatever to do with Mr. Pickering or his treatment, that he would not argue a purely medical subject with anyone outside the profession, and that he hoped Mr. Pickering and his admirers would find some other way of airing his fad than on the sick poor who are not their own masters. At the meeting on Feb. 16th some resolution of the committee was adopted *nem. con.* We do not know what the resolution was, but apparently the "system" is being adopted in the town. Mr. Bryan has protested in vain; it remains for the Local Government Board to do its duty. There is one cheering incident in connexion with this exhibition of folly, and that is that Mr. Pickering has been summoned under the Public Health Act for unlawfully exposing a patient suffering from scarlet fever by removing her in a hackney carriage on Jan. 11th. The Bench decided to convict and fined Mr. Pickering £2 and costs.

HAZARDOUS COMMODITIES.

WE have frequently expressed the opinion that the Government would sooner or later have seriously to consider the question of placing under proper control certain new and rapidly developing sections of chemical industry. Several more or less dangerous articles of chemical manufacture are becoming so largely employed in our midst for a variety of useful purposes now that some restrictions as to their sale, conveyance, and storage are, in the interest of the public safety, imperative. In this opinion we were not mistaken. Certain substances that were previously regarded as chemical curiosities have ceased to be so, and are now important commercial commodities and made on a very large scale. Thousands of gallons of "liquid" carbonic acid gas in steel cylinders under high compression may now be seen every day being conveyed in carts from place to place, and similarly other gases are stored under pressure in "tubes," as, for example, oxygen, hydrogen, nitrous oxide, and so on, all of which may expose the public to danger. Solid bricks of metallic sodium, again (kept under naphtha, of course), are every day carried from port to port as part of a ship's cargo, and very serious accidents have occasionally arisen from the intermixture of various chemicals on board ship by the damaging effect of a rough passage upon the packages. The trade in cylinders of compressed gases has already been placed under control. Still another chemical substance of comparatively recent discovery is now so extensively used as to have given rise to the necessity of a Home Office Order being recently issued. We refer to carbide of calcium, which on simply becoming moist gives off the exceedingly inflammable gas acetylene. Carbide of calcium is useful for a variety of purposes, but chiefly because on simply placing it in water it evolves pure acetylene, which possesses a remarkably high illuminating power. The employment of this method of generating a gaseous illuminant for optic lanterns, for photographic purposes, and for lighting private dwelling-houses has already been tried. It is quite obvious that some restriction should be placed upon the sale and storage of this substance, which is now being manufactured on a large scale, and which simply in a moist atmosphere gives off an inflammable gas which with air forms an explosive mixture. Carbide of calcium is now to be brought under the 14th section of the Petroleum Act, 1871, and after April 1st, 1897, it will be unlawful to keep carbide of calcium except in virtue of a licence to be obtained from the local authority under the Petroleum Act. Doubtless the recent accidents that have been reported from time to time by the employment of acetylene in this way have prompted the Home Office to issue this Order, together with a memorandum showing the character of the risks to be guarded against, and giving suggestions as to the nature of the precautions likely to be most effectual for securing safety.

SANITATION IN HUNGARY.

THE *Gyógyászat* of Budapest publishes a series of articles by the Government sanitary inspector, Dr. Jenö Farkas, on the Prophylactic Measures and Treatment of the Plague should it unfortunately reach Hungary through Turkey or Russia. Dr. Farkas has evidently been careful to follow the literature of the epidemic, and has deduced therefrom his conclusions. He estimates quarantine at its proper value—as worthless and mischievous—and insists that it is the duty of the authorities in Hungary to seriously consider and to carry out without further delay the all-important improvements in respect of dwellings, food, and general hygiene of the poorer classes. He warns the public, and particularly the medical profession, against the mischievous supposition which seems to have been adopted in some quarters as an excuse for doing nothing, that the plague bacterium is the primary cause of the epidemic and that if that be prevented from entering Europe other measures are of secondary importance. Views on hygiene, as expressed in the medical press of Hungary, coincide with those of our own. Poverty and its accompaniments of dirt, unwholesome food, and insanitary and overcrowded dwellings are hotbeds of all zymotic diseases and foci of epidemics. The high mortality and the alarming increase of tuberculosis testify to the insanitary evils present in a high degree at Budapest, and until these are seriously taken in hand and remedied they will remain a standing danger to public health, from which the inhabitants of the splendid palaces in the Hungarian metropolis will not be spared.

PREVENTION BETTER THAN CURE.

A CORRESPONDENT writes:—"In spite of all our stringent efforts to stamp out infectious diseases our large day schools are still well known to act as foci of epidemic disease. That children should be herded together, some of them possibly in the incubating stage of disease, without any medical supervision, seems incredible in the present state of science. The mere detention of a child from school from an infected house where a disease is already developed is not sufficient. Why should there not be in all our large day schools a daily medical inspection, or 'health parade,' every morning or afternoon? Local practitioners might be found in every district surrounding a day school who would, in consideration of an annual payment, devote an hour every morning or afternoon to this health inspection. The children might be placed in rows, down which the medical inspector might walk. An observant inspector would probably see at a glance signs of malaise or indisposition in a child. Such a child might be told to 'fall out,' in order that he or she might be more fully examined afterwards. Those who had passed the inspection might be told off at once to begin their classes, so as to delay the work of the school no longer than absolutely necessary. The time taken up by the inspection would, of course, vary with the size of the school

Hosted by Google

In cases of very large schools two or more medical inspectors might be employed. With regard to payment, the plan would have to be worked out in detail, as this only claims to be a 'suggestion.' In dealing with endowed schools there would be comparatively little difficulty. A board school medical inspector might be paid out of the rates. One attending a high school might be paid by means of an extra 4*s.* or 5*s.* per annum being charged. Parents would probably not grudge some small sum for the greater feeling of security against infection being brought home from school to younger brothers and sisters." The suggestion is one that is eminently sensible, and can only possibly be objected to on the score of expense. Yet if ratepayers would only bear in mind that the prevention of epidemic disease is far more economical than its dissemination, that objection could not be sustained; whilst school managers and parents would welcome the introduction of a system which would safeguard their pupils and children from infection.

TUBERCULOUS MENINGITIS AFTER HEAD INJURY.

EVERYONE who has seen many cases of tuberculous meningitis must have been struck with the frequency with which the symptoms come on after injury; but it is not often so easy to connect the two as in a case recently published by Dr. Buol and Dr. Paulus in the *Correspondenz-blatt für Schweizer Aerzte*, of which an abstract appears in the last number of the *Neurologisches Centralblatt*. A young, strong man, aged twenty-eight years, received during a fall an apparently insignificant head injury. Immediately after he developed headache, slowing of the pulse, aphasia, and finally unconsciousness, and he died fourteen days after receiving the injury. At the necropsy there was found very distinct tuberculous meningitis over the convexity of the brain, and in the centre of the tuberculous area were found two splinters of bone from the inner table. The tuberculous nature of the disease was confirmed by microscopic examination. The patient had suffered in 1893 from right-sided pleurisy and apical catarrh, and it seems almost unreasonable to doubt that the injury in this case was the means of determining the local outbreak of the tuberculous process in the brain.

"PESTIS MINOR."

IN "Some Remarks on Plague," which Dr. Lowson contributed to THE LANCET of Feb. 13th, the interesting question is raised as to the nature of certain glandular swellings which occurred at Hong-Kong during the recent outbreak of plague in that island. Dr. Lowson is disinclined to argue with Dr. Cantlie that the glandular swellings to which Dr. Cantlie referred in his paper before the Epidemiological Society were of the nature of "pestis minor" or "pestis ambulans." Dr. Lowson differentiates in these terms between these two forms of "pestis." "Pestis minor is that bubonic disease which occurs (?) before an outbreak of plague, while pestis ambulans is the designation applied to glandular enlargements occurring during or after an epidemic which may probably be due to a less potent infecting power." As to the existence or non-existence of "pestis minor" or "pestis ambulans" in Hong-Kong, we can but rely upon those observers who were present during the outbreak, and it is unfortunate that there is this difference of opinion. There can, however, be no doubt that the existence of anomalous glandular swellings during prevalences of bubonic plague is recognised by many observers and by most writers, and that there should be these anomalous expressions of the plague is what upon general epidemiological grounds is to be expected. One of the best known instances where these glandular enlargements were seen was in the outbreak of plague which occurred in Mesopotamia in 1876–77, and of which a most interesting account may be found in part 11, vol. iv. of the Transactions of the Epidemiological Society. The account is written by Dr. E. D. Dickson, physician to the British Embassy at Constantinople, and is compiled largely from the notes of Dr. Giovanni Cabiadis, which were made by him as the result of his observations at Hillat and Bagdad. In this account Dr. Dickson thus writes as to the history of the outbreak:—

"Two or three months previous to the manifestation of plague in Mesopotamia *glandular swellings free from fever* prevailed in that country. They showed themselves in the groin, armpit, or neck, and were not accompanied by other symptoms. They began to appear amongst the inhabitants about the end of autumn and continued through the winter, but towards the end of it the plague broke out and reached its acme of intensity in the spring. ..... On the cessation of the plague *apyretic glandular swellings* re-appeared again precisely similar to those which had preceded the outbreak, and they continued to manifest themselves for about two months longer. These glandular swellings were frequently met with and were distinct from the chronic adenitic swellings met with in subjects of scrofulous tendency and evidently unconnected with any special diathesis."

It is "pestis minor" or "pestis ambulans" in the above sense which the medical officers of health in such of our ports as have communication with India will do well to be on the look-out for.

"THE EMPIRE AND THE ARMY."

UNDER this heading the *Spectator* of Feb. 27th has an article with the spirit of which we quite agree. *Apropos* of the proposal to restore the name of the Royal Canadian Regiment and place its dépôt at Toronto, our contemporary says it would like to see the territorial system extended to the colonies in order to make them feel that they form a part with this nation of one and the same great organism and are taking their place under a common flag. For this purpose it is suggested that the depôt of a British regiment might be located in Australia, New Zealand, and the Cape, in addition to one in the Dominion of Canada. Setting aside the idea, which is probably destined to develop until it becomes a dominating idea, of a confederated Empire in which all shall bear a part, we should be in this way widening the area of our recruiting ground, and this is very desirable and will soon become necessary if the growing responsibilities of British rule are to be fulfilled. Our Army is a volunteer army and not maintained by conscription. When work is plentiful recruits are scarce; when it is slack recruiting is brisk. But the Army establishment is fixed by Parliament and cannot be exceeded, and the consequence is that we are constantly shifting the standard of physical requirements according to the state of the labour market, instead of taking recruits when we can get them of the most desirable kind. The British Army, it is true, shows no decadence of enterprise and courage. We have had numerous expeditions and little wars of late in which our soldiers and sailors have borne themselves as well as ever they did, but on physiological and medical grounds it is obviously very desirable that we should attract an increasing number of intelligent and enterprising young fellows of superior physique into our Army. This proposal promises to open out a way of effecting this object. Of course, there are difficulties of an official and financial nature to be overcome, but they are surely not of an insuperable kind. If we could manage to weld our colonies into closer connexion with us and get them to bear their share of responsibilities which are mutual and common to both all anxiety about the maintenance of land and sea forces on a scale adequate to our requirements would be dissipated. The statesman who could devise a scheme for accomplishing this, by opening out a career in the Army and Navy for our young colonists, or, in other words, by suggesting a method by which each of our large English-speaking

Hosted by Google

colonies and dependencies should contribute its quota to the strength of the Army and Navy, would most deservedly make for himself a great reputation. We believe that it could be done, and the trend of things goes to show that one day it will be done.

"EARTH TO EARTH BURIAL."

SIR F. SEYMOUR HADEN contributed a paper on "Earth to Earth Burial" last week at a meeting of the Church of England Burial, Funeral, and Mourning Reform Association, held at the Westminster Palace Hotel. Mr. H. D. Greene, Q.C., M.P., presided. Sir F. Seymour Haden in the course of his paper said it was absurd to enclose the bodies of the dead in hermetical enclosures, which only hindered nature's process. Properly buried the body rose from the grave in the form of elements necessary for the renewal and growth of plants. In the case of a body buried a foot deep this process was accomplished in a year, and in the case of a greater depth at about the rate of another year for every foot of depth.

BIRMINGHAM AND THE DIPHTHERIA EPIDEMIC.

WE congratulate the gentlemen who attended the meeting held at the Birmingham Medical Institute, under the circumstances described by our Birmingham correspondent in our present issue, upon the eminently satisfactory result of their deliberations. A disease so generally fatal and so insidious as diphtheria should be met and fought in every possible way, and the sooner it is attacked the sooner it will be overcome. Prompt isolation, which connotes prompt diagnosis, is the first line of defence, and the use of a genuine anti-toxic serum at the earliest possible moment is the chief weapon of attack. If Birmingham, as she is apparently going to do, provides herself with these munitions of war against disease, she may possibly reduce diphtheria to a vanishing point.

HEMIANOPSIA IN ABSCESS OF THE BRAIN.

AN interesting case is related by Lannois and Jaboulay in a recent number of the *Gazette Médicale de Paris*, in which the prominent symptoms were alexia, agraphia, word-blindness, right-sided hemianopsia, and facial paralysis. Ear disease was present, and the symptoms pointed to the presence of abscess. No pus was found at first on operating, but three weeks later puncture was again tried and a collection evacuated. Eleven days later the patient died, and a large abscess was found in the centre of the left occipital lobe and diffuse encephalitis affecting the central and frontal convolutions of the left hemisphere. There was also a small purulent collection in the third frontal convolution. The points in the case which are of special interest are that pus was not found on the first occasion, a mishap which the writers ascribe to a blocking of the hollow needle with which the puncture was made. The second point is the presence of hemianopsia, and they rightly insist upon the importance of looking for this symptom in all cases of suspected abscess. It is not unfrequently present.

RAPIDLY OCCURRING HEMIPLEGIA IN ACUTE LEAD POISONING.

DA COSTA[1] relates the following case. The patient was a woman, aged thirty-five years, in good health. Some rooms in the house, but not her bedroom, were painted, and the house became filled with the odour. From the first she complained o headache, which became so severe in three days that her medical attendant was summoned. He found that her speech was thick, the tongue slowly protruded and deviated to the right, and that there had been vomiting. Movement of the right arm and leg was much impaired, especially of the latter. This had been preceded by numbness. The loss of power increased and she was forced to remain in bed. Shortly after the right side was affected, numbness and a sense of coldness on the left side were noticed, but never motor weakness. Four weeks after the attack, when he saw her, the right arm could be feebly moved, but the grasp was very weak and the leg powerless. There was no wrist-drop, foot-drop, tremor, or muscular atrophy. No facial paralysis existed, and the tongue was protruded straight. The knee-jerks were exaggerated, especially the right. There was an increased reflex in the forearm both on tapping the flexors and extensors. There was no anæsthesia or tender spots in the course of the nerves. Tactile sensations were well preserved in the hands. With a strong light a bluish line was found on the gums, especially round the lower left incisors. Iodide of potassium and sulphate of magnesium were prescribed, and she gradually recovered. The case is remarkable in many respects. The onset of paralysis three days after exposure is unprecedented. Tanquerel des Planches[2] mentions three cases in which it occurred in eight days. The form of paralysis—viz., hemiplegia—is the rarest of all. The absence of hemianæsthesia, as far as could be observed, is unusual; so is the affection of the nervous system without preceding colic. In 102 cases Tanquerel found this to have happened in only fourteen.

PROFESSOR KOCH'S RESEARCHES ON RINDERPEST.

IN a report to the Cape Secretary for Agriculture, dated "Kimberley, Jan. 31st, 1897," Professor Koch gives an account of his investigations upon the rinderpest up to that time. He first shows that the micro-organisms discovered by Dr. Edington cannot be the cause of the disease, since inoculation with cultures of these microbes did not produce any effects and, further, animals so treated were found to be just s susceptible to subsequent inoculation with rinderpe blood. His experimental inoculations on sheep and goats, carried through several generations, did not result in any evidence that the virus had been markedly attenuated by this process; indeed, it would rather seem as if, so far as the sheep were concerned, the cultivation rather increased the virulence than diminished it. On the other hand, in the goats there was evidence of a slow attenuation. His observations upon these animals have led him to the belief that in farms infected by rinderpest sheep and goats may at first contract the disease in so mild a form as to escape notice, and that the disease becomes more virulent by being continuously propagated through these animals. This view would explain the discrepant statements made as to the liability of sheep and goats to be attacked by the disease. He found that rinderpest blood mixed with glycerine or with phenol lost its infective property, and that although in the case of an animal inoculated with the glycerine mixture the animal was still susceptible to the disease, there was a marked resistance to the effects of subsequent inoculation with unmixed rinderpest blood in an animal treated with the phenol mixture. Dilution with distilled water or normal saline solution carried even to an extreme degree did not appreciably affect the virulence of rinderpest blood. Desiccation of the rinderpest blood did, however, deprive it of its infectivity. The most interesting part of this report is that where Professor Koch shows that animals who have recovered from an attack of rinderpest are not only themselves immune from the disease, as proved by their being unaffected when inoculated with rinderpest blood, but that the blood of such immune animals exerts a protective power—for an animal

[1] American Journal of Medical Sciences, February, 1897.

[2] Traité de Maladies de Plomb, tome ii., p. 19.

Hosted by Google

"vaccinated" with the serum and blood from the immune animal proved to be insusceptible to inoculation with a large quantity of rinderpest blood. He states that further observations will be necessary before he is in a position to say how long this period of immunity can endure or whether it is possible to produce it artificially. He has not been able to find any other animals than ruminants susceptible to rinderpest, numerous experiments having been made with negative results on various species of birds and rodents. Dogs, too, are perfectly immune; but he had not completed his observations upon the pig in reference to this point. In an issue of the *Cape Times* which appeared after the number containing the text of Professor Koch's report there is some interesting correspondence between Mr. H. A. Lawrance, F.T.C., and the Secretary of Agriculture, carried on in October and November of last year, in which it appears that Mr. Lawrance, observing the immunity from a second attack possessed by animals which had recovered from one attack of rinderpest, had suggested that the blood of such naturally immunised animals might be used as a protective agent, a suggestion that is shown by Professor Koch's experiments to be supported by fact.

STRIKE OF BUTCHERS IN ROME.

THE Rome correspondent of the *Times* says that the butchers in that city have struck as a protest against the slaughter of horses for food. Great inconvenience has arisen and the price of meat has much increased, so that the poor are suffering greatly. There are one or two municipal slaughter-houses, but these are quite insufficient to supply the necessary amount of meat, and the strike is extending to other dealers in food. This is certainly a serious state of matters. There can be no possible objection to eating horse-flesh if the same precautions for procuring it sound and tender are taken as obtain in the case of ox-flesh. But the fact remains that horses used as food have generally died either from disease or have been killed to prevent them dying from accident or overwork, and the flesh of such cannot be wholesome. We have no statistics at hand of the quantity of horse-flesh consumed in Rome, but we fancy it cannot be very great, and perhaps it would be wise of the municipality to prohibit its use altogether as human food, on account of the hygienic dangers to which we have referred above.

THERAPEUTICS OF THE X RAYS.

So far the clinical value of radiography has been mainly, if not entirely, diagnostic. There are some observers, however, who, in spite of apparent discouragements, have not lost faith in its ultimate usefulness as an instrument in the actual treatment of disease. They recall the fact that in whatever way it may act sunshine (and particularly the violet rays of the solar spectrum) has been reasonably credited with a germicide property, and they expect the same result from the ultra-violet and chemically active x rays. Unfortunately for the support of this theory experiments conducted by various observers to show the action of these rays on different germ-cultures have yielded contradictory results, and have not, on the whole, confirmed the expectation that the microbes could be weakened or destroyed in this way. On the other hand, some results of clinical observations are more encouraging. The experiments conducted by Professor Lortet of Lyons and published in June of last year[1] belong to this category. In these experiments two series of guinea-pigs were inoculated with tubercle. Glandular enlargements, suppuration, and general illness followed in those not exposed to the rays, while in the others which were irradiated for an hour daily during twenty-five days no such effects were observed and the animals even gained flesh. Dr. E. Ausset, after a failure to diminish by means of the rays the activity of tubercle bacilli in a virulent culture, recently employed the same method in the treatment of a long-standing case of pulmonary and abdominal tuberculosis.[2] The patient was a child aged seven years. Her abdomen was exposed to the rays and regularly treated thus during three weeks for an hour daily. During this period she improved in general condition and gained in weight. The treatment had then to be discontinued for want of apparatus. At once there was a change for the worse in the patient's condition, and she died three weeks later. A necropsy showed evidence of advanced pulmonary phthisis with miliary tubercle in the peritoneum and caseation of the mesenteric glands. In such a case the distinction between effects *post hoc* and *propter hoc* is not easily drawn. At the same time it is to be remembered that in this instance the disease was well advanced, and that nevertheless the action of the x rays was followed by apparent benefit not otherwise accounted for. The subject is worthy of more attention than it has yet received, and Dr. Ausett's suggestion that radiography (which should be prolonged for a considerable period) may stimulate tissue resistance, and may prove distinctly useful in a case taken early, should not be too lightly set aside.

[1] Académie des Sciences.

"WALLACE-ISM!"

WE are delighted to see that the man Wallace, upon whose little ways we commented in our issue of Feb. 20th, has been mulcted in the sum of £20 12*s.* under the Pharmacy Act of 1878 for selling a poisonous drug to a person not known to him, without inquiry, without entering the fact of such sale in a book, and without being a chemist registered for the sale of such drugs. The prosecution was instituted by the Treasury, and arose out of the death of a person after taking some of "Wallace's Specific No. 1." Dr. Luff, having been supplied through the agency of a detective with a bottle of No. 1, said that on analysis the bottle proved to contain a considerable quantity of aconitine, so much so that one-sixth of an ounce would probably prove fatal. If the strength of the Pharmacopœia tincture of aconite was taken as 1, the strength of the specific would be represented by $\frac{1}{3}$. On the other hand, Mr. J. B. Cuppock, analyst to the Lancashire County Council, said that according to his analysis an ounce bottle only contained $\frac{1}{160}$th of a grain, but he admitted that this was the first practical experience he had had of aconitine. Eventually Wallace was fined in the amount mentioned above. This is some consolation, but the proper punishment for all quacks would be to make them take their own nostrums. In the majority of cases they would suffer but little harm, for most of the quack medicines are inert or, at best, somewhat aperient; in this case, however, the result might have been different. The proprietors of inert patent medicines should be fined, say, in thousands for deceiving the public by their advertisements.

OPERATIVE TREATMENT OF SPINAL CURVATURE.

CHIPAULT'S treatment of caries of the spine has been recently described in the *Therapeutische Wochenschrift*. A longitudinal incision is made over the spinous processes, so as to extend well above and below the limits of the curvature. When the processes are exposed and the soft parts drawn aside the spine is straightened as much as possible by an assistant, who pulls it into its proper position. This being done, a silver wire is passed through the interspinous ligament above the highest process to be ligated, at the bottom, near the root. The wire is then cut, leaving on

[2] Journal de Clinique et de Thérapeutique Infantile, Feb. 11th.

Hosted by Google

each side a piece twice as long as the wound. The spine is then laced up with these two ends, crossing them backwards and forwards and passing them through each interspinous ligament from the highest process downward until the lowest is reached, when the two crossed ends are twisted together. The wires must be passed through the ligaments close to the lower edge of the process above, so as to afford as firm a support as possible. The soft parts are then sutured without drainage, the wound bandaged, and the patient put to bed. This method is only applicable to moderate curvatures of recent origin, and cannot be used in long-standing curvatures or those involving many vertebræ, but the presence of an unopened cold abscess or of paralysis is said not to contra-indicate these operative measures.

SHERE EXTRAVAGANCE.

SEVEN years ago it was thought that the parish of Shere, near Guildford, ought to be drained. Difficulties blossomed like the proverbial flowers in May. A Local Government Board inquiry was held in November, 1890; another in April, 1891; and another in May, 1891. Item, £118 7*s.* 9*d.* Another inquiry was held in September, 1893—in the meantime nothing apparently happened—and a fifth in October, 1893. Item, £108 17*s.* 6*d.* Then there was another slumber until November, 1895, when a sixth inquiry cost £54 19*s.* 6*d.* Just a year later a seventh inspector "inquired," and as yet only £7 5*s.* 8*d.* has been paid for this last little luxury, but the big bill has not come in. However, in February, 1897, the Council has received permission to borrow £950 to pay for the drainage. They have already spent £290 on preparations.

A PURVEYOR OF GARBAGE.

MR. CHARLES CARRINGTON is a person who describes himself as a "publisher of medical folk-lore and scientific works." We do not know in which category he would place a book which he has had the insolence to forward to us for review, bearing the innocent title of "Untrodden Fields of Anthropology." We are not going to accord this work the honour of a review unless Mr. Carrington likes to consider what follows in the light of such. The book, said to be written by a French army surgeon, is solely a record, and a very badly written record, of garbage from the sewers of human nature. It has no scientific importance whatever. It is of no interest to the student of human nature or of natural history. We shall be happy to supply the Paris police with Mr. Carrington's address and to hand over the book with its accompanying prospectus to Her Majesty's Postmaster-General, so that he may, if he will, take steps to stay the dissemination of such abominations by the agency of his department.

PULSATING VESSELS IN THE PHARYNX.

THE recognition of this very rare condition is of importance to all surgeons. Otherwise the use of a bistoury in a case of tonsillar or retro-pharyngeal abscess or the performance of tonsillotomy may be disastrous. McBride[1] has seen only three cases of abnormal pulsation in the pharynx. The first was that of a woman aged sixty-seven years. Both pillars of the fauces pulsated. By digital examination a large arterial trunk could be traced across the posterior pharyngeal wall. The second was the case of a man who showed a fluctuating and pulsating tumour in the region of one tonsil, which was suspected to be aneurysmal, but which was a cyst resting on the carotid artery. The third was the case of a female aged sixty-one years. Pulsation was seen at the junction of the posterior pharyngeal with the lateral wall on each side. The right vessel was seen to a less degree than the left, which latter extended more towards the middle line. On the other hand, the pulsation on the right side was communicated to the corresponding tonsil. The condition of the circulatory system in general was abnormal. There were epigastric and episternal pulsations, a systolic aortic murmur, and accentuated second sound. The carotid, subclavian, axillary, and brachial arteries showed marked pulsation. The right radial was abnormal, crossing to the back of the forearm superficially to the supinator longus. There was also pulsation in the abdomen, and the posterior tibial arteries and dorsal arteries of the foot. On the skin were some small rævi as well as a tendency to diffused but patchy dilatation of the capillaries. The largest number of vascular anomalies of the pharynx have been recorded by Farlow[2]—viz., thirteen cases. All the patients except one were females, and their ages varied from seventeen to sixty-eight years. The pulsating vessels varied in position from half way between the uvula and the sides of the pharynx to the extreme right or left.

[1] Edinburgh Medical Journal, December, 1896.

SOME DEFECTS OF LONDON HOUSES.

DR. G. V. POORE holds a recognised position among authorities on practical hygiene, especially in connexion with a process for dealing with the sewage question as it presents itself in country districts. The difficulties of this problem are sufficiently familiar both in villages and in isolated houses, but Dr. Poore claims that he has satisfactorily solved them, and explains his system in his "Essays in Rural Hygiene," a very interesting book, embodying the results of several years' practical experience. In an address on the Dwelling-house, delivered at the London Institution, Finsbury-circus, on Feb. 4th, he showed that it was quite possible for a country householder to make himself independent of the sewerage arrangements devised by the officially constituted local authorities. Modern methods of sanitation as applied in towns are, according to him, attended by the serious disadvantage that they give a fatal facility for overcrowding which is certain eventually, if not checked, to do more harm than the sanitation has done good. The most obvious defects of the better class of London houses were, he said, their extreme height in proportion to the space on which they stand, the dark, underground basements, the absence of back doors for the delivery of goods or the removal of refuse, the ill-ventilated staircases, and the close "areas" shutting in the gullies leading to the sewer. The cost of London houses was also steadily increasing; an instance quoted from Marylebone showed that the rates had risen 87 per cent. in twenty-three years, and that the aggregate of the rent, rates, water-rate, and taxes amounted to over £2 per annum per square yard of occupied land.

A CASE OF QUINTUPLETS.

IN our issue of Feb. 27th (p. 590) Mr. Edwin T. Goode of Doncaster published a case of quadruplets which occurred in his practice, and we have since found that a case of quintuplets is recorded in the *Medical and Surgical Reporter* of Feb. 13th by Dr. S. J. Mathews of Mayfield, Kentucky, who states that on April 29th, 1896, he "delivered Mrs. Oscar D. Lyon of five boys, weighing respectively in the order of their birth four, four and a quarter, four and a quarter, four and a quarter, and five pounds. At birth they seemed perfectly healthy, and there was no apparent cause why they should not have lived, but for some reason they failed in health and died one by one. May 4th, at 3.20 P.M., the smallest one died, having lived only four days, seventeen hours, and twenty minutes.

[2] Boston Medical and Surgical Journal, vol. cxvi., p. 302, and vol. cxxiii., p. 6.

Hosted by Google

The second followed May 11th at 6.30 A.M., eleven days, eight hours, and thirty minutes after birth. The third died May 12th, at 11.30 P.M., aged thirteen days and two hours. May 13th, at 2.30 P.M., the fourth died, having lived thirteen days, eighteen hours, and thirty minutes; and the fifth died May 14th, at 12.30 P.M., at the age of fourteen days, two hours, and thirty minutes. All have been embalmed and will be put on exhibition for the benefit of the family, who are very poor. The mother was almost helpless for about three months before her confinement, which took place at a little over the seventh month of her pregnancy. There was one placenta, which I had photographed and preserved in alcohol. The mother has not regained her strength at this writing. Her normal weight is 112 pounds, and her height five feet one inch. She has a very dark complexion, as also has her husband. I have been their family physician for eight years, having been frequently in attendance." Dr. Mathews adds that both parents were born in Kentucky, the father in 1849 and the mother in 1857. They were married in 1874, and moved to Mayfield, Graves County, Kentucky, in 1888. They had had seven children before the birth of these five boys, the oldest of these being now over twenty years and the youngest two and a half years. The same journal also publishes a confirmatory letter from the Rev. D. F. Kerr of Mayfield, who baptised the five children.

THE RESPONSIBILITY OF PUBLIC BODIES.

ONE of the cases tried at the Hants Assizes recently was a claim in the Nisi Prius Court by a gentleman named Dent against the corporation of Bournemouth. Mr. Dent claimed £1000 as the result of damage to his property owing to the defective arrangement of the corporation's drains. He bought an estate in the valley known as the Burwood Glen in 1894, and from July of that year he was subject to a constantly recurring nuisance owing to the overflow of the sewer. Every time there was an ordinary rainfall, he said, his lawns and gardens were flooded and on the water draining off a filthy sediment remained. The cause, it was contended, was that two other drains had been connected with the sewer complained of. This was of 15 in. and 18 in. diameter, but in one place only 12 in., hence the trouble. For the corporation it was pleaded that the spot, being low-lying, was always liable to flood, and that nothing was done from 1894 until a recurrence in 1895, when, however, the necessary work was carried out. Afterwards plaintiff's garden was put in an even better state than before by the corporation's own men at a cost of £60. The sediment complained of was like that to be found on a road where a gully was blocked. In the end, however, the jury found for the plaintiff with damages at £170. We do not quite see how the sediment complained of could be like "that to be found on a road when a gully is blocked," for that sediment is only composed of road-sand and possibly horse-droppings, whereas water which overflows from sewers leaves a sediment containing all kinds of filth. It is possible that the plaintiff's garden will be found to have gained in fertility by the sewage manure, but any way we think he was fully entitled to the damages he was granted.

BIRMINGHAM AND THE FOOD AND DRUGS ACT.

THERE are some interesting items contained in that section of Dr. Hill's report dealing with the adulteration of food and drugs in the city of Birmingham for the last quarter of the past year. The proportion of articles adulterated was 24 per cent., but 15 per cent. of these were regarded as adulterated owing to the presence of preservatives. In this direction the committee appear to have taken very active measures recently and with interesting results. The following articles proved to be preserved either with salicylic or boric acid "cream," "ham and tongue," "German sausage," "Sheffield polony," "pork pies," "pickled tongue," and sundry samples of jam. An examination of certain sweetmeats disclosed the fact that "Cocoanut chumps" and "Woodbine cigarettes" were adulterated with from 2½ to 6 per cent. of paraffin wax. We have on a former occasion commented upon this objectionable practice. Finally, Dr. Hill found that a sample of chlorodyne lozenges contained no morphia, but as there is no legal standard for it he was not able to certify it as adulterated. We presume, of course, that the lozenges were purchased at the shop of a registered druggist, as otherwise had the lozenges contained morphia it would have been a proper case for bringing to the notice of the Pharmaceutical Society.

A MALFORMED TIGER'S SKULL.

ON Jan. 16th we described a series of cases dealing with irruption of teeth into the nasal cavity. We have received from Mr. Phipson, the honorary secretary of the Bombay Natural History Society, a copy of the journal of the society of Jan. 12th, which contains a letter from Captain R. Wapshare of the 3rd Lancers, describing this curious malformation as having taken place in a tiger:—

"Last hot weather," writes Captain Wapshare, "I shot a medium-sized tiger, and on examining the head I found that both canine teeth in the upper jaw were missing. The right canine tooth had evidently become decayed, as there was a hole running right up into the root of the tooth. The place where the left canine tooth should have been was perfectly smooth and covered over with the gum. It looked as if the tiger had never grown this tooth at all. I thought no more of the matter at the time, and the skull has been put away with others ever since. Yesterday I took several tiger skulls out and put them to soak in cold water previous to cleaning them, and my attention was drawn to this skull. On examining it closely I found a large canine tooth lying inside the cavity of the nose. I could only take it out with a great deal of difficulty, as it was well covered with thin bone. The tooth is a large one, but is deformed, and the point is worn rather fine, as if it had wasted away. The tooth had evidently been forced back through the socket and must have been in this state for some time because the base of the tooth had become deformed. It must have originally been in its normal position in the jaw, as it shows the enamel as in an ordinary tooth, and this also goes to prove that the injury took place after the animal was full grown. I may mention that in order to remove the tooth I had to extract it through the nose."

TYPHOID FEVER DISSEMINATED BY A DRINKING FOUNTAIN.

THE localised outbreak of typhoid fever in the town of Halstead, a report of which by the medical officer of health for the county (Essex) will be found in another column, is of considerable interest, inasmuch as the origin has been traced to the use of water supplied by a public drinking fountain which had become specifically infected with the sewage from an isolation hospital in which there were patients suffering from typhoid fever. That the outbreak was not of a much more serious character was due to its occurrence during the very cold weather, when drinking fountains are little resorted to, and to the very commendable promptitude of Dr. Gordon Roberts, the medical officer of health, in plugging up the tap immediately his suspicions were aroused. This water had been observed to become turbid after the heavy rains of Dec. 2nd and 4th, indicating that the supply was liable to pollution. The District Council ordered a sample to be analysed, but as a "fine weather" sample was selected for this purpose very little organic matter was detected and the analyst reported that he did not think any suspicion could be attached to the water. Dr. Roberts did not regard this as satisfactory, and

Hosted by Google

the county medical officer was consulted. He pointed out the absurdity of relying upon such an analysis and the danger of acting upon the report. He asserted that the mere fact of the water becoming turbid after a heavy rain was in itself a proof of intermittent pollution, and recommended that the cause should be immediately ascertained. With some reluctance this advice was acted upon, and it was then discovered that the fountain water was being from time to time polluted with the sewage from the isolation hospital. It is to be regretted that some analysts still persist in giving opinions as to the safety or otherwise of drinking waters submitted to them for examination based merely upon the results of their analyses. This practice cannot be too strongly condemned. In this particular instance no analysis of a "fair weather" sample could justify an opinion that the water was free from suspicion. Fortunately, however, the common sense of the medical officer of health had more influence than the analyst's opinion; and an epidemic, which might otherwise have become serious, was nipped in the bud.

A MINISTRY OF HEALTH.

WE have been asked to comment on a proposal that a Minister of Health should be appointed and that his department should include the following: (1) The Registration department; (2) the Local Government department; (3) the Factory and Workshop department; (4) the Analytical and Chemical department; (5) the Veterinary department; (6) the Public Works and Prisons departments; and (7) the Lunacy department. The proposal we believe to be generally sound, except that we recognise that as an "interest" a strong claim could be made for the veterinary department to retain its connexion with the Board of Agriculture. On the other hand, however, there is increasing evidence of relationship between the health of human beings and the health of the lower animals, and for the purposes of progress of knowledge as to this relationship, and particularly for the purposes of the institution of a proper and sufficient health administration, there would be distinct advantage in the association of the veterinary department with the Minister concerned in the protection of human health. But it is not clear to us on what grounds it is proposed to bring under the control of the same Minister the functions of the Office of Works, though some re-arrangement of duties might, of course, have to be made. There is another office which must eventually be made, which must be thought of in connexion with this subject, viz., that of the Medical Officer of the Government. At the present time Dr. Thorne Thorne ably fills the office of Medical Officer of the Local Government Board, but for all purposes of making international arrangements for the prevention of disease the Government has no adviser. At the present moment Dr. Thorne is acting in this capacity in Venice, but by no stretch of imagination can this be regarded as one of the functions of the Medical Officer of the Local Government Board. The Foreign Office has obviously to borrow from the Local Government Board the officer who is appointed for an entirely different purpose. With any constitution of a Ministry of Health we presume there must be also a re-arrangement of this branch of the work of the Foreign Office. Among the proposals on which we are asked to comment is one that the Minister of Health should be appointed for life—that is, he should not go out of office with the Government, and that he should have a seat in Parliament. These suggestions we do not regard as practicable. He should, we think, enter Parliament by the ordinary method and have Cabinet rank. Without being a Cabinet Minister his opportunities would be enormously diminished, and it is obvious he could not occupy this position if he were not in political sympathy with the Government in office.

AT a meeting held at the Royal United Service Institution on Saturday, Feb. 27th, a provisional committee was formed to obtain the protection of H.M. Forces in India from contagious diseases. The following are among those who have joined this committee:—Sir James Fergusson (chairman), General Sir Havelock Allan, V.C., Sir Terrence O'Brien, K.C.M.G. (Hon. Treasurer), Admiral Sir Edmund Commerell, V.C., Brigade-Surgeon Lieutenant-Colonel Hill-Climo, M.D., R.U.I., Sir Henry Cunningham (vice-chairman), Major-General Dashwood, Surgeon-Major-General Hamilton, Sir James Hills-Johnes, V.C., Colonel F. C. Keyser, C.B. (Hon. Sec.), Dr. J. F. Payne, Lord Raglan, Mr. Shillitoe, Hon. Evelyn Ashley, and Viscount Downe.

THE meeting of the Ophthalmological Society on March 11th is to be devoted to a discussion on Retro-ocular Neuritis. Mr. Marcus Gunn will open the debate, and the medical aspects of the subject will be discussed by Dr. Buzzard. Dr. Gowers, Mr. G. A. Berry (Edinburgh), and Dr. Hill Griffith (Manchester) will also take part. We are asked to state that medical men who are not members of the society will be welcomed as visitors.

A LETTER from the Clerk of the Privy Council, Sir Lennox Peel, was read at the meeting of the Executive Committee of the General Medical Council, postponing the hearing of the appeal of the Apothecaries Hall of Ireland against the decision of the Council not to appoint assistant examiners to Monday, March 22nd, 1897, at 11 A.M.

AT a special meeting of the staff of the Medical School of Guy's Hospital a resolution was adopted expressing the hope that the Government would this session introduce a measure to appoint a Statutory Commission for the reconstruction of the University of London in accordance with the report of Lord Cowper's Commission.

A MEETING was held on Saturday last at the Museum of the Royal Botanic Society of London, at which Mr. W. Martindale, F.C.S., read a paper on the Desirability of Establishing an Institute for Teaching Botany in the Royal Botanic Gardens.

MR. H. M. CROOKSHANK, M.R.C.P. Irel., F.R.C.S. Edin. (Pasha), Director-General of Egyptian Prisons, has been selected by the English Government to succeed Mr. Hamilton Lang, C.M.G., as British Controller of the Daira Sanieh.

IT is announced, says the *Times*, that Lord Iveagh has subscribed £12,500 to the commemoration fund for providing trained Queen's nurses for the Irish poor, in addition to a like amount to the Prince of Wales's Hospital Fund.

TUBERCULOSIS IN BRIGHTON.—Speaking at the annual dinner of the Brighton Butchers' Association on Feb. 24th, Dr. Newsholme, the medical officer of health, gave some figures as to the meat condemned in the town during 1896. Owing to the coöperation of the butchers the number of animals condemned was larger than in any previous year. Yet the total was only 49 out of an estimated total of 120,000 animals killed in the town, or about 1 in 2400. Of these only 26 were condemned for tuberculosis. He expressed the opinion that hopes of Government compensation for such animals were groundless. He suggested a system of insurance against such loss, or combination to buy only animals which were completely warranted. Every butcher would thus become a sanitary inspector, and this plan he favoured of the two; it would attack the evil at its fountain head, and bring pressure upon farmers to remedy the evil condition of byres, &c., which now served to propagate these diseases.

The Lancet Special Commission
ON
THE METROPOLITAN WATER-SUPPLY.

III.[1]

THE CHELSEA WATERWORKS COMPANY.

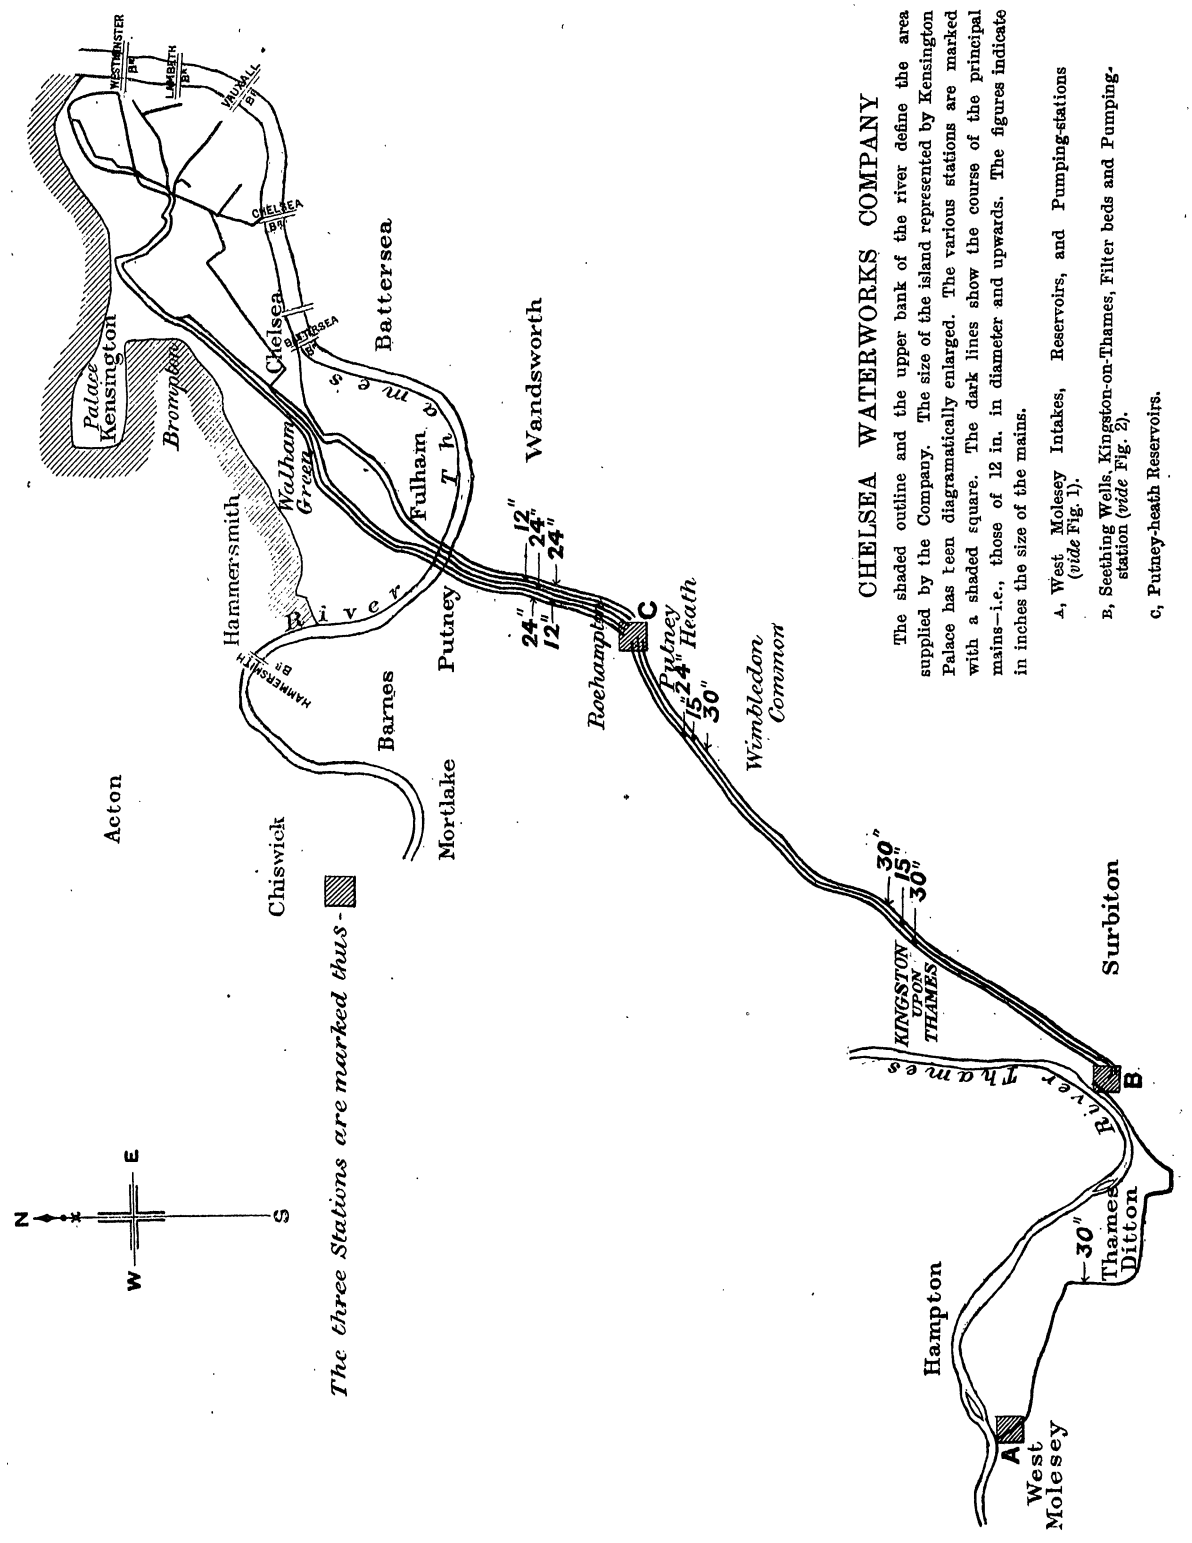
History.

THE Chelsea Waterworks Company dates from the reign of George I. In 1722 an Act was passed for better supplying the city and liberties of Westminster and parts adjacent with water. By this Act commissioners, undertakers, and trustees were appointed for effecting the works necessary for bringing water from the Thames into canals and ponds, from which it was to be raised into convenient reservoirs between Oliver's Mount and Hyde-park. The commissioners and trustees were formed into a corporate body under the title of "The Governor and Company of Chelsea Waterworks." In 1723 George I., by letters patent under the Great Seal, appointed the commissioners and granted a charter to enable the Company to raise the necessary funds for carrying out the work. In 1726 the company was authorised to convert two ponds in St. James's-park into reservoirs and in 1727 to construct a reservoir in Hyde-park. In 1733 the authorised capital of the company was increased and the company was obliged to keep books of account. By the year 1726 considerable progress had been made in the work, and the canals made from the Thames served to supply reservoirs in St. James's-park, so that Whitehall and parts of Westminster were supplied with water in August, and the engines were of sufficient power to raise the water to the reservoir in Hyde-park. This reservoir was capable of holding 25,000 hogsheads (or 1,350,000 gallons) of water, and the one in St. James-park held almost as much, so that the company was "in a condition to serve upwards of 10,000 houses with water at a cheaper rate than the New River Company or any other company at that time." The advertisement of the company asserted that if there were no other water to serve the cities of London and Westminster and parts adjacent they would be able to supply the whole as soon as their pipes could be laid for that purpose. The severe winter of 1739–40 caused much trouble, and "a variety of unforeseen obstacles and difficulties occurred." The works were frozen up or destroyed by the severity of that dreadful winter. In 1767 the amount of water raised was 784,000 gallons, and in 1809 1,456,000 gallons daily. In 1809 an Act was obtained to enable the company to take water from the Thames near Ranelagh Creek and to lay pipes in the river bed for a distance of 240 feet, so that water might be obtained below low-water mark. At this time the water was distributed without purification; later it was allowed to subside in settling reservoirs before distribution.

The first filter bed in London was constructed in the year 1829, and was designed by Mr. James Simpson, engineer to the Chelsea Company. Mr. Simpson made a variety of experiments during the years 1825–26 and in the following year began experiments on a larger scale, being desired by the directors of the Chelsea Company to direct his whole attention to the subject. It may be interesting to describe the first filter bed that was made in London. It occupied about one acre, its sides were formed with brickwork, and it was supplied by reservoirs which had an area of about one and a half acres. The water was first pumped into the subsiding reservoirs and passed from them to the filter bed, the water being allowed to flow through small pipes without disturbing the sediment. By this means, to quote a contemporary account, "the greater part of the extraneous matter being separated by the deposition of its feculence whilst standing in the reservoirs the water rapidly percolated through the gravel and sand of which the beds are formed. ..... The filter bed before being filled with water had the appearance of several channels parallel to each other formed by banks which are broad at the bottom and gradually slope on each side to a point at the top." The sides were built of brickwork and the filtering material was formed of three different strata of gravel and sand laid over brick tunnels; the tunnels were built without mortar. Immediately over the brickwork fine gravel was laid, above this finer gravel mixed with coarse sand, and on the top fine sand. Each of these layers was 2 ft. in thickness, so that the water passed through 6 ft. of filtering material. The sand and gravel were washed before they were used. The fine sand used at the top had the advantage of removing the feculent matter which was chiefly deposited on its smooth surface, and the accumulated sediment was easily removed by scraping. It was found that the matter deposited discoloured the sand for a depth of about 3 inches, but the greater part of the matter was deposited on the surface, so that when half an inch of the upper layer of sand only was removed it renovated the efficiency of the filter. It was found that the inclemency of the seasons did not affect the action of the filter, and that when the ice was several inches thick filtration went on uninterruptedly.

About the year 1826 considerable improvements were made in a reservoir which the Company possessed in the Green-park. Mud, which had been collecting in it for several years, was removed, and the reservoir was deepened. The bottom of the reservoir was lined with hard bricks cemented together and it was surrounded by a brick wall. At this time also the machinery for regulating the sluices was altered and a very "ingenious contrivance" invented by Mr. Simpson obviated the necessity of replacing the upright pipe which formerly stood at its western extremity, and is shown in a characteristic drawing of Rowlandson, now in the print room at the British Museum. The path round the reservoir was at the time a fashionable promenade. The length of the reservoir was 220 yards, the width 35 yards, and the space occupied with all its appurtenances was about two acres. The height above Thames high-water mark was 45 ft. At this time about 25,000 tons of water were usually stored in the reservoir, although it was capable of holding a larger amount, and the engines pumped up the water every four days. The mains were 10 ft. below the surface of the water when the basin was full and served to supply houses in Westminster and Pimlico.

In 1852 an Act entitled "The Chelsea Waterworks Act of 1852" was passed. It authorised the Company to take water from the Thames at Seething Wells, in the parish of Kingston-on-Thames, and to construct new works in that parish, and allowed water to be taken from Chelsea Reach until the work was finished. Filter-beds were constructed at Seething Wells and mains laid down to conduct filtered water to service reservoirs on Putney Heath, from whence it was distributed by gravitation, passing across an aqueduct over the Thames at Fulham. These works were completed in 1856. In 1875 an Act was obtained to enable the Company to remove their intake from Seething Wells, which is below the junction of the Mole with the Thames, to West Molesey and to put up the necessary works there for that purpose. These were completed in the autumn of 1877.



Present State: General Description.

The Chelsea Waterworks supply Fulham, Walham-green, Chelsea, Belgravia, Pimlico, and part of Westminster. The district is bounded on the west and on the south by the Thames, and extends along the bank of the river from the Crab Tree public-house to the lower part of Northumberland-avenue; the northern boundary runs along Crown-lane and the Old Brompton-road and Knightsbridge adjoining the districts supplied by the Grand Junction and West Middlesex Companies, and on the east the district supplied by the New River Company. The intakes are at Walton, West Molesey, and Surbiton. There are subsiding reservoirs at Molesey and filter beds at Surbiton. After filtration the water is pumped to reservoirs on Putney Heath; from Putney it passes over the bridge between Putney and Fulham and is then distributed by gravitation.

The intakes.—The chief intakes are at Walton and West Molesey on the south bank of the Thames. (See Fig. 1, B and A.) The water first passes through a 1 in.-grating. The gratings are 6 ft. in width and 3 ft. in depth. Of these gratings there are fifteen, and they are placed three deep. The gratings keep out the coarser impurities—for example, leaves, small pieces of wood, &c. They are cleansed from the river side from a boat. From the intake two 36-in. pipes pass under the towing-path into the company's grounds, which adjoin the towing-path.

[1] Nos. I. and II. were published in THE LANCET of Feb. 20th and 27th, 1897, respectively.

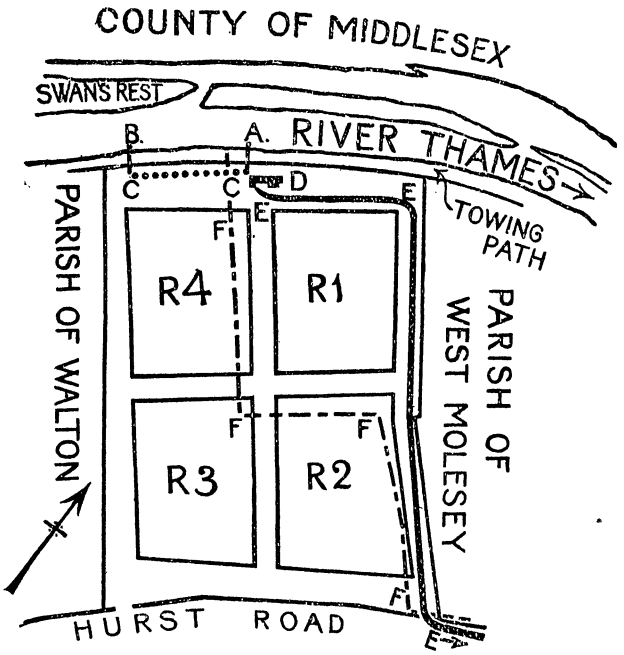
CHELSEA WATERWORKS COMPANY

The shaded outline and the upper bank of the river define the area supplied by the Company. The size of the island represented by Kensington Palace has been diagramatically enlarged. The various stations are marked with a shaded square. The dark lines show the course of the principal mains—i.e., those of 12 in. in diameter and upwards. The figures indicate in inches the size of the mains.

A, West Molesey Intakes, Reservoirs, and Pumping-stations (*vide* Fig. 1).

B, Seething Wells, Kingston-on-Thames, Filter beds and Pumping-station (*vide* Fig. 2).



C, Putney-heath Reservoirs.

Hosted by Google

The pipes are controlled by two regulation cocks. The water first passes into a well through five bays. The bays are 6 ft. on inside measurement and are fitted with screens. Some of the screens are of galvanised iron, the newer ones are of copper wire. The screen used is an unusually fine one containing twenty-five meshes to the square inch. The frequency with which the screens are cleansed naturally varies according to the state of the river; sometimes it is found necessary to cleanse them twice a day. When the river is in a comparatively pure state it is not thought necessary to clean them more than twice a week, or even less often. Through the screens the water passes into a brick culvert of which the dimensions are 4 ft. 10 in. by 4 ft.

The Molesey intake (Fig. 1, A) has outside screens similar to those which have already been described. The water

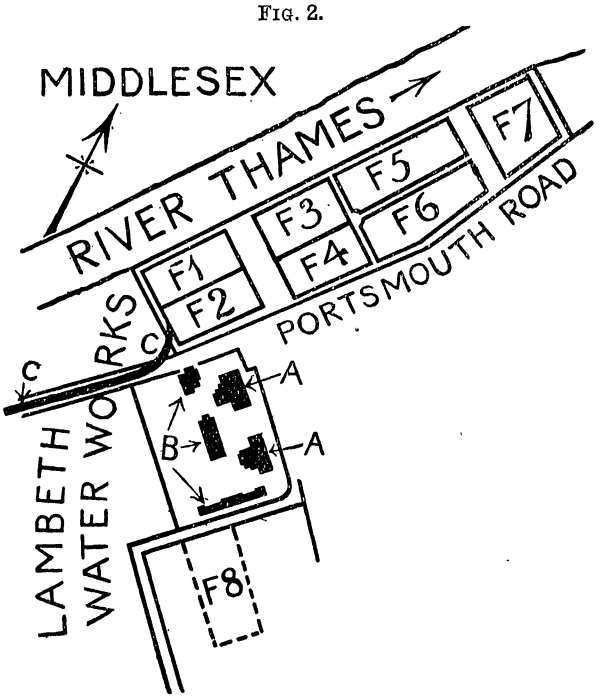
FIG. 1.

Walton and Molesey Station. A, The new intake (West Molesey). B, The old intake (Walton). C C, Brick culvert into which the gravel water flows. D, Engine house. E E, Main which conducts water to Seething Wells (Kingston). F F, Parish boundary. R 1, R 2, R 3, R 4, Reservoirs.

passes by two 30-in. pipes into a tank 20 ft. in depth through a number of screens 6 ft. by 4 ft. The screens are fastened on iron frames which are fixed into grooves. From the tank the water flows into the engine house.

Water from the gravel bed.—There is a brick culvert extending from the old to the new intake. (See Fig. 1, C C.) This culvert is used for obtaining a certain amount of water from the gravel. At the sides of the culvert iron valves are arranged. When these valves are raised the water can flow through the stratum of gravel into the culvert. The culvert is 75 ft. from the river and has fifteen valves in it—that is to say, there are fifteen places through which the water can pass into it from the gravel bed. The gravel beds just outside the culvert are in part artificially made; larger sized stones were placed in the immediate neighbourhood of the inlets into the culvert. It is found, practically, that little water can be obtained from this source except during the times when the Thames is at flood. When visited on Dec. 8th the river was 4ft. above its normal height and the gravel water was being used and it was understood that no water was being taken directly from the river and that the water which was going to Seething Wells was derived entirely from the subsiding reservoirs and from the gravel beds. The Thames on this day (Dec. 8th) was very turbid, but the water derived from the gravel was almost clear.

Engine house.—The engine house contains a Worthington engine of 150-horse power, which can pump 24,000,000 gallons daily into the reservoir. In the same house there are two vertical engines of 50-horse power each, which work bucket and plunger pumps. The steam is generated by six Cornish boilers and one Lancashire double flue boiler.



Subsiding reservoirs.—The water from the Thames is pumped into four subsiding reservoirs. These are situated between the Thames and the high road (Fig. 1, R 1, R 2, R 3, R 4). They are more or less square in form. Each has an area of about ten acres, and is capable of holding 35,000,000 gallons. The water is first pumped into one of the two reservoirs which are next the river; having remained there for some time it is allowed to flow into the second, then into the third, and finally into the fourth. It is found that the reservoir into which the water first flows contains a deposit three or four times as great as that found in the fourth reservoir. From Molesey the water flows by gravitation, or is pumped through a 36-in. pipe to Kingston.

Seething Wells, Kingston.—The Kingston station contains the filter beds and the engines which pump the water to Putney (Fig. 2).

Filter beds.—There are seven filter beds having a total area of seven acres. Each filter is capable of holding about 1,100,000 gallons of water. The rate at which water is usually filtered is 1¼ gallons per square foot per hour. The sand is washed by a hose and jet, under a pressure of 200 ft. of water.

Engine house.—The engine house contains two Simpson's double-action pumps of 150-horse power, and two bucket and plunger pumps of 150-horse power. The steam is generated by thirteen Cornish boilers. Another engine house contains four Simpson's engines of 600-horse power working bucket and plunger pumps. At one time the intake of the company was at Kingston; now all the water is usually taken at West Molesey and Walton, and having passed through the subsiding reservoirs there goes as described to Kingston. The old inlets by which the water was formerly taken from the Thames at Kingston remain, and are used in cases of

emergency. From Kingston the filtered water is pumped to covered reservoirs on Putney-heath.

Putney-heath reservoir.—The property at Putney-heath consists of eight acres situated at a height of about 177 ft. above ordnance datum. There is a stand-pipe by means of which an additional head of 22 ft. of water can be obtained. There are three reservoirs having a total capacity of 11,000,000 gallons. From Putney-heath there are three 24-in. pipes and two 12-in. pipes, which pass through Putney and over the bridge between Putney and Fulham to Chelsea

Hosted by Google

and distribute the water. The main pipes pass in the direction shown in the plan.

Area of Supply.

The Act of 1852 authorises the Chelsea Company to supply the following places:—

Supplied: Brompton; Buckingham Palace and the precincts; Close of the Collegiate Church of St. Peter, Westminster; Kensington Palace and precincts; St. James's Palace and precincts; and Scotland Yard.

Partly supplied: Chelsea; Fulham; Kensington, St. Mary Abbott; St. George, Hanover-square; St. James, Westminster; St. John the Evangelist, Westminster; St. Margaret, Westminster; St. Martin-in-the-Fields; Whitehall; and Westminster Palace and precincts.

Not supplied: Hammersmith; Liberty of the Duchy of Lancaster; St. Mary, Paddington; St. Anne, Soho; St. Clement Danes; St. George, Bloomsbury; St. Giles, Bloomsbury; St. Giles-in-the-Fields; St. John the Baptist, Savoy, Strand; St. Marylebone; St. Mary-le-Strand; St. Paul, Covent Garden; and Savoy precincts.

The following table gives the average daily supply per head and the dates of the maximum and minimum supply per head for the years 1895 and 1896. It will be seen that in both these years the maximum supplies were given during the month of July, but the minimum supply in 1895 occurred in January, and in 1896 in February.

TABLE I.—*Showing Average Daily Supply.*

Year.	Average daily supply per head.	Maximum		Minimum	
		Month.	per head.	Month	per head.
1895	43.05 gallons	July	47·96 gallons	January	38·45 gallons
1896	42·90 gallons	July	51·80 gallons	February	38·70 gallons

Length of pipes.—The length of the company's mains in December, 1896, was 245·91 miles.

Number of hydrants.—The number of hydrants erected during the year 1895 was 333; during the year 1896, 322; and the total number on Dec. 31st, 1896, was 1386.

Communication with other companies' mains.—There is a communication with the main of the Grand Junction Company, near St. George's Hospital, Hyde-park-corner.

Houses under constant supply.—The number of houses under constant supply on Dec. 31st, 1894, was 23,314; on Dec. 31st, 1895, 27,104; and on Dec. 31st, 1896, 30,787.

Total number of houses supplied.—The total number of houses supplied by this company on Dec. 31st, 1894, was 36,941; on Dec. 31st, 1885, 36,941; and on Dec. 31st, 1896, 37,362.

Percentage of houses under constant supply.—On Dec. 31st, 1895, the percentage of houses under constant supply was 73·00, and on Dec. 31st, 1896, 82·00.

New Works in Progress and Projected.

Filter bed.—A new filter bed is in course of construction at Surbiton. (See Fig. 2, F 8).

New main.—A new 36-in. main is being laid from Molesey to Seething Wells, Surbiton.

OUTBREAK OF TYPHOID FEVER TRACED TO SPECIFIC POLLUTION OF A WATER-SUPPLY.

BY JOHN C. THRESH, M.D. VICT., D.SC. LOND.,
MEDICAL OFFICER OF HEALTH, ESSEX COUNTY COUNCIL.

THE following brief account of a localised outbreak of typhoid fever is of considerable interest inasmuch as the origin has been clearly traced to the use of a spring-water which had become polluted by sewage at a time when the sewage was specifically infected with the excreta of one or two persons suffering from that disease.

The outbreak occurred in the small town of Halstead, in the northern portion of the county of Essex. The town is supplied with water from a deep well in the chalk. There are a few shallow wells still in use, and on Mount-hill, on the northern outskirts of the town, there is a public drinking fountain by the roadside fed by the subsoil water collected on the hill. The surplus water from this fountain is piped to some works in the town, and supplies the cottage of a workman who resides on the premises. The only persons who use this water for domestic purposes are the inmates of this cottage, and the fountain is little used in the cold weather save by children in passing to and from school. Near the top of the hill and above the source of the spring supplying the fountain an isolation hospital has recently been erected. On Nov. 17th a baker, who is constantly driving about the country, was notified to be suffering from typhoid fever, and on the following day he was removed to the hospital. On Dec. 7th a daughter of this patient was notified and removed the same day. How the baker became infected we have been unable to ascertain. On Dec. 28th the man residing at the cottage supplied with water from the Mount-hill spring was attacked. As he had had no communication with the baker's family and had not been away from the town for over two months, a local cause was strongly suspected. The water-supply came under suspicion inasmuch as it had been observed that early in the month, after a heavy rainfall, the water was turbid. As such a condition had never before been observed it necessarily was remarked. As soon as suspicions were aroused the water was examined by the chemist at the works, and at the request of Dr. Gordon Roberts the Urban District Council caused two samples to be examined by a local chemist, one sample being taken from the fountain and the other from a small tank into which the water flows to feed the fountain. At the time these samples were taken the water had again become clear. The analyses proved satisfactory, the local chemist certifying that the analytical data "are in both cases quite satisfactory and do not afford any indication of contamination, the quantity of organic matter actually present being in each case extremely small and insignificant. Examined microscopically nothing objectionable could be detected in either. ..... I do not think any suspicion can be attached to either water." Between Jan. 22nd and 30th four children residing on Mount-hill were notified to be suffering from typhoid fever, all of whom acknowledged to drinking more or less frequently at the fountain when passing. As the water had on several occasions been observed to be turbid after rain, and no other cause save the use of the water seemed capable of explaining the dissemination of the infection, Dr. Roberts plugged up the fountain tap and wrote asking my assistance. After my visit and at my request every other probable cause, such as the milk supply, attendance at any party or school treat, &c., was investigated, but with negative results. Recognising the futility of examining the fountain water when it had become clear, I asked that a sample of the water when next observed to be turbid should be taken and sent to me; meanwhile I recommended that the pipes conveying the water to the tank and fountain should be traced and uncovered to discover the cause of the turbidity which resulted after a heavy rain. A few days after a sample of the turbid water was sent me, and the District Council ordered the pipes to be uncovered, after debating the necessity for such action for some time. The pipes conveying the water were found to cross over the roadway, passing under the sewer (leading from the isolation hospital and cottages above) and almost in contact therewith. They consisted of ordinary agricultural drain pipes, whilst the sewer was of earthenware with "plugged" joints, and four of the pipes nearest to and over the water pipes were damaged. The sewer was laid twenty years ago, but it appears probable that the pipes were only broken some six months ago, by the passing over of the steam road roller. During dry weather any leakage from the sewer might not directly enter the water pipes, but during heavy rains the escape would be considerable, and would pass straight into the land drain or water pipes, and so contaminate the water supplying the fountain and infected cottage.

The turbid water upon analysis proved to be very impure, the organic ammonia and oxygen absorbed being very much higher than in samples previously examined. Bacteriologically the water was carefully examined to detect the presence of the bacterium coli commune and the bacillus typhosus. The growth in phenolated broth was rapid and abundant. From this a phenolated plate culture was made which gave a large number of colonies, none of which liquefied gelatin, and which in appearance resembled those of the bacillus coli and typhosus. Certain of these in a gelatin culture produced gas bubbles, others did not, and these latter when grown in broth did not produce indol. Compared with the typical typhoid organism no test which we were able to

Hosted by Google

apply revealed the slightest difference, and I have no doubt in my own mind that the water actually contained the typhoid organism. As the hospital contained typhoid fever patients from the middle of November there is little doubt that the water became infected during the heavy rains of Dec. 2nd and 4th, and has been infected from time to time since.

On Feb. 6th another child was attacked with typhoid fever. Four children in this house attended the same school, but only the one attacked had drunk the fountain water, and this on several occasions when passing on his way to and from a pond upon which skating and sliding were going on during the frost.

The above outbreak exemplifies in a marked manner the danger arising from placing too great reliance upon the analysis of a water. The very fact that the character of the water in question was so markedly influenced by a heavy rainfall was sufficient to excite the gravest suspicion, and any opinion based upon a fine-weather sample was bound to be misleading.

HISTORICAL NOTES ON MEDICINE, SURGERY, AND QUACKERY.

I.

IN the diary of Nicholas Blundell of Crosby, near Liverpool, we find several medical men mentioned. On July 27th, 1702, he records that "My Father went after diner to wate of my Lord Molineux at ye New Stand, where he was sodanly taken so very ill that he sent for me to wate of him home and bring ye Coach for him. July 28th. I sent for Dr. Farington to come to my Father, but he was not to be found. July 29th. I went to Wigan and brought Doctor Frances Worthington along with me to Crosby. Aug. 1st. Coll. Edm: Butler came from Durham in his Way to Ireland, he sent to Wigan for Doctor Tho: Wor: who came late that night. I sent Tho: Howard to Whit-Church for Doctor Bostock, but he came not." Valentine Farrington, M.D., a younger brother of Wm. Farrington of Worden, Esq., resided at Preston. Dr. Thomas Worthington is mentioned in "A Cavalier's Note Book," the cavalier being Mr. Nicholas Blundell's grandfather. Dr. T. Worthington died Nov. 27th, 1702. He was practising at Wigan in conjunction with his son Francis when he was summoned to Crosby. Dr. Bostock of Whitchurch had a considerable local reputation. Doctors, however, "were in vain," for the patient died on Aug. 2nd. "About half an Hour after Tenn in ye morning being Sunday, many People in the Roome hearing Mass, and Mass just almost finished, My Dearest Father departed this life, being much lamented by all; as his life was virtuous and edifying, so was his Death. Sweet Jesus Receive his Sole." On Oct. 17th the diarist "was at ye Buriall of Doctor Tarlton's Wife." The Tarletons were an old Liverpool family, one of the streets in the town being named after them. On March 15th, 1703, Mr. Blundell receives a visit from Dr. Lathom, who "came hither to shew ye Petission wch was presented to ye Queen by Mr. Bannerd Howerd in behalf of ye Said Dr. Lathom," &c. Dr. Lathom had practised surgery in Liverpool and his wife Judith had kept a school; but the penal laws being against them as Roman Catholics they were persecuted by the town officials. In 1686 a royal mandate was issued in their favour. It was addressed: "To all the archbishops & bishops, & to their Chancellors and Commissaries, & to all other persons, exercising ecclesiastical Jurisdiction, & to the *Custos rotulorum*, Judges of Assize & gaol delivery, Justices of the peace for our County of Lancaster, & to all other officers and persons whom it may concern. James Rex, 15th March. Whereas we are informed that Richard Lathom, of Leverpoole, in our Countie of Lancaster, Chirurgeon, & Judith his wife, who keepes alsoe a boarding schoole for the education of youth, at Leverpoole aforesaid, have latelie been molested or prosecuted or threatened to be soe, for, or in respect of, their exercising the said severall vocations without license, or by reason of their religion, being Roman Catholics. Now wee being assured of the loialtie of the said Rd. Lathom & Judith his wife, & of their abilitie to exercise their respective vocations, we doe hereby authorize & license them to use & exercise the same respectively; & our pleasure is, and we doe hereby direct you, & everie of you respectively, to supersead & forbeare all prosecution against the said Rd. Lathom & Judith his wife, for or by reason of his exercising the art of chirurgerie, or his or their keepinge a boarding schoole, or socouring, teaching, or educatinge youth; & if anie sentence is or hath bene given or pronounced, or penalty recovered against, or fine sett upon him or her, for, or touching the premises, our pleasure is that the same be discharged, & that you permit and suffer ye sd Richard Lathom & Judith his wife, & each of them quietlie to exercise the said severall vocations without anie molestation or disturbance whatsoever, & for soe doing this, or the entire or inrolment thereof, wth or before you respectivelie shall bee unto you & everie of you respectivelie a Sufficient warrant. Given att our Court at Whitehall ye fifteenth day of March in the second yeare of our raigne. By his Maties. command.—SUNDERLAND." The subject of Dr. Lathom's petition above mentioned is not stated. He retired to Aintree, where he died in 1713.

Mr. Blundell, having married "Lord Langdale's Doughter" at Hathrop, carried his wife home to Crosby in a "Charriot." On July 2nd, 1703, he says: "I came from Colebrook, bated at Warington, was met by Dr. Lathom & treated by him in ye Road. I brought my wife to Crosby. July 8th. Sr Wm Gerard, Merchant Houghton, & Dr. Tarlton dined here." In August he was with his wife at Lathom "Spaw," which was destroyed by the sinking of coal shafts early in the present century. It was situate opposite what is now called Spaw Farm in Lathom. It was in good repute during the last two centuries. Dr. Borlase of Chester wrote two treatises in its praise and sent copies to "the Cavalier," who wrote in reply: "To these waters next under God I do certainly owe my life. 'Tis now about four or five weeks since I gave them another visit by reason of our old acquaintance. I was pretty well when I went; I drank them eleven or twelve days & returned perfectly well home. Yet I find them somewhat costly, for my stomach is so good that I eat all before me." This was in 1672. "Jany 4, 1704. I went," remarks the diarist, "to see Parson Richmond, found with him Mr. Marsden, Mr. Danvers, and Mr. Poole of Leverp: I think Parson Rich: had nuly been cut for ye stone." (Parson R. was father of Dr. Hy. Richmond.) "Jany 23rd. My wife sent for Dr. Fabius, he said she was with child." (Dr. Daniel Fabius lived at Low Hill.) "Feby 5th. I hunted about Litherland and Walton wth Leverp: Doggs in Company of Mr. Silvester Richmond & Mr. Molineux of Leverp: we had a long Chace." "Feb. 19th. I saw Ri: Jump married to Cath: Fisher." "Feb. 20th. She quarrelled with me about her not tacking Phisick & my not coming to see & pitty her." "May 2nd. Dr. Shaw & Mr. Edw. Molineux of Formby shot Rooks with Stonbows at Ince." "May 12th. I went to Ormskirk to ye Buriall of Dr. Barton." On the 27th he went to Wigan and lodged at Dr. Worthington's. "June 13th. I went to Low Hill to ye Doctors & to Leverp: I drunk wth Mr. Gleast & Dr. Tarlton; it was a wet night." At Holywell on June 25th he "went into ye Well with Severall of ye Pilgrime Sisters &c. Smiths by name in Sropshire." "July 3rd I was at Great Crosby Race between Mr. Silv. Richmond's Bay Mair and Mr. Atherton's Gray." "July 14th. I went to advise with Dr. Fabius, I dined there, thence went to Leverpoole." "July 20th. I rode to Adams Spaw to drink the waters." "Nov. 3rd. Mr. Guildus came to draw a Tooth for my wife." "April 11th, 1705. I went with my wife to Dr. Fabius." "June 22nd. I tryed an experiment wth eleven living Miss [mice?] in a hot pot." "July 10th, Uncle and Aunt Gerard &c Lodged here."

Dr. Gerard had settled as a physician in Durham and married Bridget, youngest daughter of the "Cavalier." He was of the Garswood family. "August 7th. I went to Speak [Speke] to wish Joy to Mr. Norris, I dined there, and called at Aigbourth." Dr. Norris had been married on July 12th to Anne, sole daughter and heir of Peter Gerard of Crewood, co. Chester. Dr. Norris's grand-daughter married Rich. Pennant (Lord Penrhyn). "August 14th. I gave 6*d.* in presence of ye two Mr. Witheringtons to Mrs. Aspinwall ye Midwife, for wch she is to give me six Guineys whensoever she is Married to anyone."

Silvester Richmond was evidently of a sporting turn, for the diarist records under date, May 15th, 1706, "I was at ye Great Plate at Lev: where Lord Molineux his Hors beat Mr. Sil: Richmond's Maor, I drunk a horsback with Alderman Tyarer, &c." In 1706 we find him visiting his uncle Dr. Gerard at Durham; then playing at bowls with Dr. Edward Norris of Speke, Lord Gerard, and Sir Thos. Aston. In

Hosted by Google

January, 1707, he says, "My wife went to Mrs. Bootle of the Peele to show her her finger that was burned." Mrs. Bootle appears to have been a sort of amateur lady doctor, for in July we read, "Mrs. Bootle of ye Peel came to Blood me for my fall." Probably she was an ancestress of the present Earl of Lathom. The Silvester Richmond so frequently mentioned by the diarist was probably a son of the physician of that name, who died in 1692. Further on, under date 1727, he is called "Old Sil: Richmond." Early in the present century there was another Sil. Richmond, who wrote election squibs. He was a searcher in the Customs and the "prince of Liverpool wits."

The following entries are interesting as showing the habits of medical men and squires of the last century:—"Mar. 10th, 1707. I made Coz: W. Ge: Salve alias Captain Midletons for a Bruse or Cut. April 3. Dr. Fabius came to see Tho: Gower, he let him Blood. Sept. 20th. At Leverp: I drunk with Dr. Tarlton, James Houghton, and Wm. Atherton. I payed 20*s.* at ye Exchange Coffyhous for a Periwig. October 10th. Mr. Aldred and I came from Hooton, Dr. Tarlton treated us with Wine at his own house, Mr. Plumb tryed his Lamp with two Weaks. Oct. 13th. Mr. Plumb and Dr. Tarlton came to Cource with me. Decr. 18th. Doctor Tarlton came to Great Crosby and sent to borrow my Grewhounds. Mar. 8, 1708. We called to see Parson Wairing, he was trobled with ye Stone and Gravell. April 10th. Mr. Ald: (his R. C. Chaplain) shaved my head. April 17th. I dined at Mr. Plumbs; he and Doctor Tarlton drunk with me at ye Woolpack. April 24th. I went to Leverp: and drunk at Dr. Tarlt: wth him Parson Stith and Mr. Walsh. June 19, 1708. One and twenty Adders were taken on my Midings. June 21st. I sent Mrs. Ann Rothwell with a Present of 22 Adders to ye Doctors of ye Low. [This would be Dr. Daniel Fabius of Low Hill.] June 23rd. Mrs. Bootle blodyed my Wife. I gathered some Flowers for Flowering Great Crosby Cross tomorrow. June 24th. My wife and I were at the Flowering of Great Crosby Cross. I Steeped my Feet in hot Whey for about two Hours to make my corns come out by ye Roots, but I think 'twill doe no good.' July 12th. Darby Wife brought a picture for Mr. Aldr: Alter-peece from Dr. Lathom's which he had lent me." On July 26th Mr. Blundell and other Roman Catholics had to appear before Dr. Norris and two other "Justises of ye Peace" at Ormskirk Sessions to Compound to prevent conviction on account of their religion. "Augt. 30, 1708. I began ye first time to make Milk Punch. Sept. 13. I went to Ormkirk to see Dr. Gerard. Oct. 29. I made up some Doses of Powder for ye Falling Sickness for Mary Pilkington's sister. Nov. 9th. I dined at Mr. Aldreds with Mr. Moston, Mr. Thornton, and Dr. Worthington, it being ye Doctor's birth day he gave us a bole of Punsh. Nov. 16th. I Began to make a dose of Phisick for Wm. Tompson for ye Dropsy. April 1st, 1709. I went to Leverp: and sold my Rabet skins to Leversage. Mr. Scofild, ye apothecary, gave me some Jue Jubs and Date Stones. May 1st. Duke Bluddyed my wife, Rich: Johnson, Wm Gray, I, &c., were present. May 7th. I went to Leverp: I set a great while wth Mr. Sil: Richmond at his Hous, we discoursed about Planting, sowing Cole Seed and improving Grond. May 13th I sowed one Buss: of Barley in ye Cowhey dressed with Oyle and other Ingredients as Powder of Coleseed, &c., but it did not answer expectation. May 17th. Mr. Silv. Richmond came hither, I went out with him to look at some ground to see if it was proper for Coleseed. July 11th. Ince Gardiner helped Jo: Banister to Innoculate. Augt. 7th. I went to Dr. Lathom's and asked him for a Receipt for one at York Schoole." The difficulties of travelling in those days are described in the following account of a journey to Whitchurch to consult Dr. Bostock. "August 18th, 1709. My wife & I began our Journey toward Whit-Chourch, we came too late for ye boats at Leverp: so we went over at Runkhorne, after wch we lost our way & went to Windy Weston, where we got a guide that brought us to Fradsom. Aug. 19th. We went from John Webster's, the signe of ye Bear's Paw, at Fradsom to Whit-church to Mr. Benbow's, ye signe of ye Red Lyon, where we dined and discoursed Dr. Bostock about my Wive's Paine in her back. From Whitchurch we went to Chester, where we lodged at Mr. Taylor's, ye Signe of ye Golden Lyon. August 20th. We saw several of ye Paletines in the Wool-hall, &c. We dined at Chester & thence went to ye Rockhous, but the Boat was gon, so we got a Smoke made, but no Boat coming to us we went to ye Wood-side, where Mr. Darcy Chantrell came to us and got a Boat for us, so we came home. Sept 3rd. I wated of Dr. Clayton at his Brother's. Jany. 9, 1710. Dr. Smithson came to see me and let me blood. Feb 6th. I Rosted my Steeped Wheat to make Coffy on, but it did not doe well. April 29th. I went to Leverp: & drank at Mr. Silv: Richmond's with him & Parson Foxcroft, who was formerly Curate of Sefton. June 8th. We met Mr. Blundell Coming home from Dr. Bostock. June 15th. Went to Leverp: & saw ye play acted called *Sephonisba;* or *Haniball's Overthrow.* I discoursed Dr. Smithson about his Ordering too much Lodinum for Mr. Lancaster. June 16th. I began to still some Eye-bright. June 24th. Dr. Cawood the Oculist from Dublin came to look at my Eyes; he Lodged here. June 28th. I went with Doctor Cawood to Leverpoole to assist him in geting Acquaintance & to procure a Chamber for him where his Patients may Come to him; we drank at the Post Office with Doctor Smithson, Doctor Person, &c. July 14th. I began to learne of Dr. Cawood to play at Picket. July 17th. Dr. Cawood & I went to Prescot; I went to Mr. Oliver Lime to know whether he would venture with Dr. Cawood for his Eyes; we light at the Signe of ye Ship & discoursed our Land-Lord, Tho: Moss. July 20th. I Began by Orders of Dr. Cawood to take Drops, Eye-bright Tea, and to put Clary Seeds into my Eyes. July 22nd. Dr. Caw: and I went to Leverp: we Looked at ye Dock that is in making, & we went to see ym make White-Mettle Mugs. July 24th. Dr. Caw: went to ye Flowering of Ince Cross. August 10th. I waired 24*s.* in Chinea in my Hale for my Wife. Mr. Ald: Dr. Cawo: and I went to the Grange Greene & saw a Match Boweled there between two young Men of Ince & two old Fellows of Formby, a Slave come from Turkey was on the Green. Oct. 20th. Widdow Bolton a Chirurganess Came hither to dress a cut that Fanny has got over her Eye. Nov. 30th. I Went to Chorley Town to meet young Mr. Gerard of Highfield and Pothecary Gerard's Son [I fancy that Pothecary Gerard's son was destined to be the physician who invented Everton Toffee]. Jany. 27th, 1711. I went to Leverpoole with my wife, &c. We saw ye great Saxon Maxemilian Christofer Miller. I drank at ye Wool-pack with Mr. Plumb, Mr. Allison, and Dr. Fabius & with Mr. Ford ye Putear, Dr. Traps &c."

It is astonishing the number of medical men with whom this worthy squire dined, played at bowls, and hobnobbed. Mrs. Blundell appears to have had more faith in lady quacks. "March 12th. I cut a good deale of Eye-bright for me to smoke. March 30th. Rich: Cartwrit lett my Wife blood in ye foot. April 24th. My Wife rid behind Mr. Ald: (the priest) to Dr. Lathom's to prayers, they dined there." (Dr. Lathom, being old and infirm, had a private chapel at his house at Aintree.) On May 1st he mentions that "Cap. Sidall, Dr. Farrington, &c., played at Inn and inn" at a coffee-house. "In" signified that there was a doublet, or two dice alike out of the four; "In and in" that there were either two doublets or that all of the four dice were alike, which swept all the stake. "June 3rd. Mr. Ald: and I went to Ince to welcome home Mr. Blundell from Whitchourch." (He had been to consult Dr. Bostock and died very shortly after this visit.) "June 18th. My Wife went to Mrs. Bootles of ye Peele to shew her a Soar place she has in her Legg. Jany. 16, 1712. I went to Aintry and looked at Doctor Lathom's Housing called Aintry Hous to see in what repair it was in. Mar. 27th. Rich: Cartw: let me blood. March 30th. Being extreamly ill of a Continuall Fit of Heckoping which lasted for about 15 Hours without ever any Long intermission both Dr. Will: Lancaster and Dr. Andrews came to me. April 1st. Doctor Lanc: came to see me. I got up being on ye mending hand. May 23rd. My wife went to ye Peele to shew her foot to Mrs. Bootle which was soar with being bluddied." Mrs. Bootle's treatment must have been successful or the "soar" very slight, for a month later he records: "My wife began her journey towards Holywell; she Rid to Leverp: and designes to walk the rest." "July 7th. I was very busy most of ye afternoone shaping Tinsall, &c., for the Garland for my New Marl-pit and after Supper ye Women helped to paste some things for it. I began to teach the 8 Sword Dancers their Dance wch they are to Dance at ye Flowering of my Marl-pit. Dr. Cawood played to them." (There were grand preparations going on for some days, with plenty of music & dancing, and on the 15th July a large bull was baited in the Marlpit, the bull behaving to admiration, "not above two Doggs but what were very ill hurt.") "July 31st. I went to Mr. Ald: where I found Mr. Tho: Ford ye Puterar, Jack Whit ye Barber, Doctor Barret and Pothecary Lathom." It appears that this Thomas Ford, a Brazier, could write his name upon a wall at arm's length

Hosted by Google

with half a hundred weight hanging at his little finger. "Sept. 18th. Dr. Caw: helped me to examain my Simballing things. Sept. 21st. I called at Dr. Lathom's & Chaptered Betty Lathom about her unkindness to her Uncle & Aunt. Feby. 24th, 1713. I went to Wigan & discoursed Doctor Tho: Worthington about seting his Hous ready Furnished, it was for my Brother Langdale. June 12th. I took a Drought of Sack and Oil but found no great good by it. June 13th. I went to Leverp: with my Wife, she showed her Legg to Mrs. Maginis. June 24th. I being one of Dr. Lathom's Executors I went to his Hous to order his Buriall, he was carried on my Coach Carriage to Walton Church; there was at his Buriall Jo: Tyrer, Mr. Bower & his Wife, Mr. Crisp, &c.; there was at the Hous Mr. Shaw of Ormsk: John Crew, &c. July 8th. I met Ri: Tatlock & sold him some of Dr. Lathom's Chirurgicall Instruments. Novr. 17. I took some of ye Picturs as were Dr. Lathom's to Ned Howerd's, some of them I hung up there in ye Chappell. Jany. 5th, 1714. I removed ye Ship in ye Hall & Charg'd ye Gunns against tomorrow. Jany. 6th. Mr. Plumb, Doctor Lancaster and I, &c, was at Mrs. Anns Cocking, there were three Battles. Tatlock was here, we had a Merry-Night and Fier'd ye Gunns of my Ship. Jany. 11th. I took in hand to Cure Ginnet Blundells Legg. but she did not long continew my Pasient. Augt. 2, 1714. Tho: Kerklington ye old Simpler of Herbs, & Picture Seller lodged here. Augt. 5th. Mr. Gilb: Barrows Pothecary of Leverp: Dined here. Sept. 11th. I went to Leverp: with Mally & got a Rotton Tooth of hers pulled out by a Mountebank. Jany. 26th, 1715. I gave a Poore Woman a Doce for ye Falling Sickness. April 23rd. I shewed Dr. Only my Reel and Bottle and my Little Calf, and some other of my Curiossitiss. Augt. 14. I dined at Mosburgh wth Black Dr. Lanc: and Cap: Rob: Faz: Parson Low came to us, Oct. 19, 1715. Duke let my Wife blood in her Arme. Oct. 29th. We expected the Hors Militia to come Serch here. Oct. 31. I came not in till dark Night expecting a call. Nov. 16th. I set in a Streat place for a fat man. [The house was searched by the soldiery and Mr. Blundell was hiding; a little later he left home, made his way to London, thence to the Continent, where he and his family lived for some time.] Oct. 6th, 1717. It being near Full Moon I cut my Wive's Hair off. Dec. 9, 1718. Mr. Bower made some proposalls to me for the Purchass of Dr. Lathom's Fifteen Aiker. Dec. 13th. I went to Leverp: and drank with Mr. Rech at ye Wool-pack; he is to be Land-Lord there. Pothecarry Par gave Jolly Brown & me a Bottle of Wine at his Hous. May 14th, 1719. I went to Ormsk: and shoed my Toe to the Mountebank Dr. Fry, I drank at the Swan with Dr. Lancaster. [It would have been better had he "shoed" his toe to Dr. Lancaster and drank with the mountebank.] Nov. 14th, 1719. I dined at the Woolpack in Lev: with four Strangers, I suppose they were Londoners; I saw Matthew Buckinger, who was born without Hands or Feet, I saw him writ very well with his Stumps and tipe very dexterously some nine Pins down & play Tricks of Leger-de-Mesne; Mr. Whitley & Mr. Bayron went with me to see the Little Man play his Tricks. [The Squire himself sometimes entertained his friends with tricks of "Leger-de-Mesne."] Dec. 23, 1719. I went to ye Buriall of Wm Bawer, but came too late so that I met ye Corps & went to Sefton; when the Buriall was over I stayed drinking at the Aile-Hous with Dr. Lancaster, Selsby of Ormskerk, Young John Yates. Feb. 3rd, 1721. I Scoaped 30 Leomonds, ye Juce of them made one Pint, & about the fourth of a Pint, I put to it one pint of Brandy. I also made some shrub; the proportion was Brandy 2 Qts., Crab Vargious 1½ pt., leomonds 6, Dubble Refined Sugar 1 lb. The proportion of mixture for my last Brue of Aqua Coelestis was Brandy 2 Qts., Crab Vargeus 1 Pt. and ⅛th of a Quart, Lime Juce ⅛th of a Qt., Lisbon Sugar 1 lb., Leomonds 3, and being the Brandy was very good I put to it 4 Qts. and 1 pt. of Water, the water was first bouled, the outward Rine of the Leomonds was infused into it, so they were also in the Shrub, but the Brandy and Leomond Juce had not any Rine infused in it. This Night I had a Cargo of 16 Larg ones brought to Whit Hall." The worthy Squire, although he moved in the best society in Lancashire, was not above doing a little contraband business occasionally. On April 3rd, after the funeral of Widdow Maile of Maile, he "stayed drinking at ye Ail-Hous in Sefton Church Yard a good while with Doctor Lancaster, Richard More, &c." "May 10th, 1721. I sowed some Cowcomber Seeds; they had been steeped in New-Milk about twenty-four Hours." On July 8th he and Mrs. Blundell travel to Holywell and on the 9th he says: "My wife & I went into ye Well, I was much out of Order after I came out & Continewed so for some Hours." "Sept. 2nd, 1721. We called at Ormkerk & wished Joy to Dr. Lancaster & his Wife recently married. Sept. 15th. I gave Pat: Clifton [the priest] some Eye-Balsom being one of his Eyes is very bad. Oct. 12th. Being Pat: Gelib: [Father Gellibrand probably] took Phisick to-day we dined with him in his Roome. Jany. 16th, 1722. I saw young Mr. Yats & Doctor Orme set William Marrows Thigh, he broke it yesterday coming from Preston Faire. June 8th. Tho: Marrow, Junior, showed Betty Bolton his Thumb and Rob: Weedow his Foot, I had them both in Cuar. Sept. 1st, 1722. I Burned above one Groce of Pipes in ye Washhous Grate. I mixed some Pouders together for Convultion Fits." He plays bowls and drinks at Crosby with Apothecaries Lathom & Parr; dines at Wooton with Dr. Lawson of Chester, and is Visited at Crosby Hall by Mr. Blundell and Dr. Molyneux and their wives. This does not prevent him from "faulting" the two gentlemen later on for shooting near his wood. "Jany. 31. 1723 My wife went to Leverp: to show her finger to Betty Bolton Feby. 22nd. I made my Incomperable Salve for a Cut or a Bruse. March 2nd. I discoursed Mr. Peters concerning removing Will: Sumner's Doughter out of ys towne ere she be delivered. March 23rd. Mr. Sadler payed me £50 for ye Purchas of Dr. Lathom,s late Hous and Teneament. May 26th. We went over from Leaverp: in Eastom Boat and dined at Hooton with Dr. Low, thence to Chester. Augt. 26th. I went with my Doughters to Bartholomew Fair, we saw a Droll, a Little Man & a Popit Play. I met Lawyer Culcheth, Dr. Eyre and Sr. Franc: Anderton at the Castle Tavern in Drury Laine. Sept. 9th. My wife & I saw Humphrey Anger & Joseph Midleton Hanged at Tyburn. Sept. 10th. We four made a Viset to my Lady Westmoreland at Twitnam and dined there. Coming home we were overturned, Fanny's Arme & my Side was hurt, Surgeon Gihee let me blood. Sept. 16th. Mally & I saw the Corps of Mr. Fetherston carried in Forme by ye undertaiker. Oct. 29th. Pothecary Livlesley came hither & desired I would make use of him being I had made use of Mr. Latham his Master for my Apothecary. April 22, 1724. Pat Bartlett let Mally blood. Augt. 14th. Before three this morning I disturmbed two Cupple of Woosters Jane Withington, Nelly Howerd & their Sparks. August 15th. Mat: Withington came to chapter his Doughter for Courting in ye Night. Augt. 17th. Jane Withington & Nelly Howerd left their Service, they went to Darby [West Derby] Waikes. August 30th. Margarit Gray was Seased this Morning very ill after the same Manner as several of the Neighbours are, & in the Evening she took a Vomit. Novr. 2nd. Dr. Augier came ye first time to see me. [Dr. Samuel Augier, an eminent physician, resided in Union-street, so called from the union of Sir Cleave Moore with Ann, daughter of Mr. Joseph Edmund.] Decr. 4th. Fanny & I went to Wigan to be under Dr. Francis Worthington, our health being very bad; the coach was overturned, & when we came neare Wigan it was laid faste ye Rode being so deep, so we left it in ye laine al Night, and we went with our Horses to Wigan where we Lodged at Kendall's, the Leggs of Man. Jany. 17th, 1725. My wife and Mally went to Leverpoole with Fanny she is to be under the care of Dr. Bromfield. She Lodges at Mrs. Williamson's. Feby. 13th. Fanny was so ill of ye Convultion Fits that Mr. Aldred gave her the Holy Oyles. Dr. Ferniho of Chester met Dr. Dickins here, they had a consult. June 6th. Fanny had one of her Violent Convultion Fits, it was occasion'd by seeing a Mous in her Roome. June 9th. I went with Dr. Bromfield and Pat: Hardesty [priest] to Crosby, I bowled four Bowles out of Hand against Mr. Cripps' three. ..... I came directly home without going into the Aile hous. July 27th. Mrs. Bravarius came to look at my Wive's Legg. [She was housekeeper at Ince Blundell.] Sept. 25th. It being Fanny's Birth day Tatloc play'd here; we danced both before and after supper. Mr. Hen: Blundell sup'd here, we play'd with him at Chaising ye Whistle. Sept. 27th. She drank too much Burch Wine. Jany. 12th, 1726. 'Pat Bartlet Lanced Mary Molineux in her Gumbs for the Tooth-Aich, and mixed some Powder of Roman Vitriall with her Blood.' [The operator in this case was a priest.] Jany. 23rd, 1726. Mr. Livlesley sent his Brother hither with some Phisick; he fell in Rimrose as he came. Jany. 30th. Roscow went to Ince to show her lame Arme to Mrs. Prevarius [the housekeeper]. April 1st, 1726. We began to make some Wine of 60 Sivell Oringes and 30 Leomons; they cost 6s 8d.; four doz. Pound of Lisbon Sugar cost £1 4s. It made six dozen Bottles wch comes to 5s. 1¼d. p Doz. May 1st. From Ormskirk I went with Fanny to Coz

Hosted by Google

Gillib of Astley, where she is to stay for some time for Change of Aire in hopes to Cure her Ague-Fits. Augt. 2. Apothecary Livsey and his Brother the Churcheon who is lately come out of France made me a Visit. Sept. 13th. Dr. Clayton, son to Daine Clayton in Ireland, and Lawyer Radcliff dined here. Pat: [Father] Curedon went hence to live at Sefton and to help at Croxtath, he has ben a Gest here, I think more one yeare. Sept. 30th, 1726. Coz: Butler and I went a Fox-hunting with Lord Molineux, there was Surgeon Livsey, Dr. Rice, &c. Oct. 28. I had seaven Lads of this Town beaton at my Gate-Hous with a Sterrop-Leather, some by their Fathers, others by their Masters and some by other Persons, for Stealing my Apples and for other Peevish tricks. Jany. 21st, 1727. I went to Leverp: and made Major Broadnax a viset; he told me that in March next he will be 108 years of Aige, he has his Memory perfectly well, and talks extreamly strongly and heartally without any seeming decay of his Spirrits. [He died in the following January and was buried at St. Nicholas's Church.] March 27, 1727. Lord Barrymore went abroad upon Business. Old Sil: Richmond and his Doughter dined at Rocksavage. April 12th. I went to Crosby Greene; there was Parson Brooks, Parson Davys, Bannion of Ormschurch, Mr. Haymar, Doctor Bromfield, &c.: there were several Cocks brought from Leverp: and Ormsch: which fought upon the Green, I saw three or four Battles. June 11th. I was at prayers at Mr. Tempest's of Broughton, Dr. Traps was there. June 8th. I put the Leaves of Whit Lillys into two Glass-Bottles, they are to make Oyl on for a Burn or Scald. March 23rd, 1728. Mr. Chisleton, Dr. Ferniough, &c., came to my lodging (Golden Talbot in Chester); I advised with him about Mally's eyes and mine and about Fanny's Laimnes. Coz: Butler and I made a Viset to Sr Hen: Bunbury, we drank there with Mr. Semor Chalmondeley, &c."

On April 4th the diary closes abruptly, though the genial squire lived nine years longer and doubtless had many drinks and games at bowls with physicians, "apothecaries," parsons, and other neighbours. He does not appear to have been the source of much profit professionally to the medical men of his acquaintance. The rest of the diary is extremely interesting and valuable as a faithful picture of the period in which the diarist lived. He had a decidedly good time of it on the whole in spite of the religious disability he laboured under.

THE PARIS CARNIVAL: NEW SANITARY REGULATIONS.

THREE years ago we pointed out some of the dangers to health which attend the Paris Carnival.[1] We then explained that the old Carnival had to a great extent died out. Formerly the butchers, wearing fancy dresses, paraded a fat bullock in the streets of Paris on Shrove Tuesday; but the weather is doubtful so early in the year, and the butchers and their bullocks did not awake any very keen interest in the minds of the Paris population. The students were better inspired when they sought to organise another Carnival in Mid-Lent on the day consecrated to the patron saint of the washerwomen. The dirty work of a laundry is perhaps scarcely more poetic than the slaughtering of cattle. However this may be, it will be readily understood that the youths of the Paris University are much more interested in the fête day of the laundresses than in that of the butchers. Thus it has come about that the Mid-Lent Carnival eclipsed in its brilliancy the more ancient Carnival held on the butchers' day. This year, however, the butchers have made a strenuous effort to come to the fore again, and instead of one street Carnival and cavalcade there are two cavalcades. Now the special feature or the new feature of these Carnivals is the Battle of Confetti. The confetti consist of small discs of paper about a quarter of an inch in diameter, with which since we last wrote on the subject the British public have, in their turn, become familiar. We explained that though this paper is extremely light yet about a million kilogrammes of confetti were thrown in the streets of Paris at the Mid-Lent Carnival of 1894, and that 3,500,000 *serpentins* of paper were likewise employed. As these ribbons of paper measure in length about 75 metres each, sufficient paper ribbon was used in the course of one single day to encircle the world six times. We pointed out that the throwing of so much paper in the streets had a tendency to clog the sewers. But what was more serious was that to avoid the expense of buying confetti many persons picked up handfuls from the ground. In thus using the ammunition twice over they naturally gathered up dust, small gravel, and dirt of every description. The throwing of confetti into people's faces was therefore attended with considerable danger. People's eyes were injured and their faces cut. But the greatest success that can be scored in encounters of this sort is to surprise someone who is imprudently shouting or speaking and to quickly discharge a handful of confetti into his or her open mouth. If the confetti are clean, no great harm is perhaps done; but if they have been scraped up from the pavement after many persons have trodden upon them, then the practice is at once dirty and dangerous. This practice also led to quarrels. Many persons naturally resented receiving showers of dirt and pebbles, so that good-humoured frolic soon degenerated into street squabbles. Since 1894 the authorities have been greatly troubled to find a practical means of dealing with these grievances. To suppress the confetti altogether would have been a very unpopular measure, so efforts were made to water the streets and render it impossible for people to pick up the confetti. But this made a horrible mess and tended to spoil the costumes of the masqueraders. Also the watering apparatus could not be brought to bear in the midst of the dense crowd where the fun was fast and furious and where it was most needed. This year, however, the authorities have hit upon an extremely ingenious device. The Prefect of Police issued orders that anyone throwing or selling confetti of mixed colours was to be arrested. Thus the bags contained confetti of only one colour. The purchaser might buy blue, red, green, or yellow confetti according to his fancy, but he could only throw one colour at a time. A similar regulation is in force in Belgium. On the other hand, the contents of the bags as they fall get mixed, and thus any confetti picked up from the pavement would be of various colours, for they would come from different bags. In this manner those who picked up old confetti, either for the purpose of throwing or of selling them again, could at once be detected and the abuse stopped. The weather proving exceptionally fine, all Paris joined in the fête. Besides, the cavalcade was really well worth seeing. To impart an aspect of historical romance the fat ox stood under a Druidical altar and was accompanied by Celtic warriors. When to this is added that there were some 11,000 masqueraders and many cars in the cavalcade, notably one consisting of a painter's palette twenty feet long on which female forms gracefully reclined and by the colours of their dresses represented the paint on the palette, it will be seen that there was attraction enough to bring together an immense crowd. This only rendered the necessity of sanitary precautions the more urgent, and it is satisfactory to know that means have at last been found to ensure that the Battle of Confetti shall be fought with clean, unsoiled confetti.

[1] See THE LANCET, March 10th, 1894. "The Sanitary Aspect of the New French Carnival."

BUBONIC PLAGUE IN INDIA.

THE total returns for Bombay up to Feb. 25th, according to a telegram through Reuter's agency, amount to 7638 cases and 6198 deaths. The week's mortality from all causes up to that date was 1650, as compared with 1728 in the previous week.

The latest official telegram on the subject of plague received by the Secretary of State from the Governor of Bombay is in continuation of that of Feb. 21st. We extract the following information from it:—"Deaths from all causes in Bombay city for the week ended Feb. 26th, 1525; reported plague deaths, 730. For the week ended Feb. 25th 102 dwellings condemned, 130 recommended for alterations, tiles removed from 1216, floors dug up in 604, and 2029 limewashed, 393 vacated, 38 destroyed by fire, and several otherwise demolished. The distinct reduction of the total number of deaths a satisfactory sign, but some of the people who left Bombay are now returning from infected places outside and have re-infected places which had become almost free. People entering Bombay as well

Hosted by Google

as leaving will have to be examined and watched, and steps to this end are being taken. The two new hospitals are opened. Similar steps will have to be taken in regard to people leaving Poona, where plague is much worse than was feared and has rapidly increased. It has so far been found impossible to get an accurate statement of deaths from plague in Poonah, but in January deaths from all causes were 497, against quinquennial average of 261. Up to Feb. 26th deaths were 882, against quinquennial average of 225. The most drastic measures will be enforced and aid of military called in. In the Thana and Surat district plague shows tendency to spread. Plague still severe in Coorla, Bandra, and Bhiwandi."

Sporadic cases of plague have been reported at some other districts and places for the week ending Feb. 26th. Quarantine camps have been established at railway stations in Sholapur district, and fairs and pilgrimages in the Bombay Presidency have been stopped where necessary.

"At Karachi plague deaths for the week ended Feb. 26th 205. Effectiveness of measures taken increasing; opposition of people diminishing. No indication of general spread of plague in Sind."

Dr. Rogers Pasha, chief of the Egyptian Sanitary Department, has returned to Cairo from Bombay, whither he had gone to study the conditions of the plague. He believes that the danger of infection to Egypt is not so great as was at first supposed, and that, seeing how slowly it travels, measures similar to those adopted during last year's cholera may be relied upon to control it. The sanitary conditions of the chief towns of Egypt are, in his opinion, worse than those of Bombay.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6642 births and 4096 deaths were registered during the week ending Feb. 27th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 20·8 to 18·8 per 1000, rose again last week to 19·4. In London the rate was 19 0 per 1000, while it averaged 19·7 in the thirty-two provincial towns. The lowest rates in these towns were 12·8 in Huddersfield, 13·3 in Brighton, 13 5 in West Ham, and 13 6 in Halifax; the highest rates were 23·1 in Bristol, 23·2 in Oldham, 24·0 in Liverpool and in Salford, and 24·1 in Norwich. The 4096 deaths included 379 which were referred to the principal zymotic diseases, against 336 and 316 in the two preceding weeks; of these, 120 resulted from whooping-cough, 88 from diphtheria, 65 from measles, 41 from diarrhœa, 32 from scarlet fever, 32 from "fever" (principally enteric), and 1 from small-pox. No death from any of these diseases was recorded last week either in Brighton or in Halifax; in the other towns they caused the lowest death-rates in Croydon and Blackburn, and the highest rates in Salford, Bolton, Birmingham, Sunderland, and Plymouth. The greatest mortality from measles occurred in Salford, Bradford, Bolton, and Plymouth; from scarlet fever in Leicester; and from whooping-cough in Wolverhampton, Birmingham, Burnley, Sunderland, and Bristol. The mortality from "fever" showed no marked excess in any of the large towns. The 88 deaths from diphtheria included 62 in London, 4 in Birmingham, and 3 in West Ham. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three large towns. There were 43 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, Feb. 27th, against 21, 38, and 34 at the end of the three preceding weeks; 18 new cases were admitted during the week, against 12, 20, and 3 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2817, against 3050, 2901, and 2815 on the three preceding Saturdays; 237 new cases were admitted during the week, against 245, 226, and 227 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 373 and 335 in the two preceding weeks, rose again last week to 368, but were 183 below the corrected average. The causes of 67, or 1·6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Oldham, Bradford, Newcastle-upon-Tyne, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 28·8 and 25·5 per 1000 in the two preceding weeks, further declined to 25·3 during the week ending Feb. 27th, but was 5·9 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12 4 in Leith and 17·8 in Greenock, to 28·7 in Glasgow and 30·7 in Perth. The 756 deaths in these towns included 32 which were referred to whooping-cough, 30 to measles, 13 to diarrhœa, 5 to scarlet fever, 5 to diphtheria, and 1 to small-pox; in all, 86 deaths resulted from these principal zymotic diseases, against 105 and 119 in the two preceding weeks. These 86 deaths were equal to an annual rate of 2·9 per 1000, which exceeded by 1·1 per 1000 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 28 to 42 in the three preceding weeks, declined again to 30 last week, and included 24 in Glasgow and 5 in Edinburgh. The deaths referred to whooping-cough, which had increased in the five preceding weeks from 26 to 45, declined to 32 last week, of which 19 occurred in Glasgow, 4 in Edinburgh, 3 in Dundee, and 3 in Aberdeen. The 5 fatal cases of scarlet fever exceeded by 1 the number recorded in the preceding week, and included 4 in Glasgow. The deaths from diphtheria, which had declined from 5 to 2 in the three preceding weeks, rose again to 5 last week, of which 2 occurred in Glasgow and 2 in Dundee. The fatal case of small-pox was registered in Leith. The deaths referred to diseases of the respiratory organs in these towns, which had been 240 and 218 in the two preceding weeks, rose again to 231 last week, and exceeded by 111 the number in the corresponding week of last year. The causes of 45, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 41·2 and 43·4 per 1000 in the two preceding weeks, declined again to 37·6 during the week ending Feb. 27th. During the past eight weeks of the current quarter the death-rate in the city has averaged 40 3 per 1000, the rate during the same period being 18·8 in London and 22·5 in Edinburgh. The 252 deaths registered in Dublin during the week under notice showed a decline of 39 from the number in the preceding week, and included 55 which were referred to the principal zymotic diseases, against 58 and 72 in the two preceding weeks; of these, 34 resulted from measles, 12 from whooping-cough, 3 from diphtheria, 2 from scarlet fever, 2 from "fever," and 2 from diarrhœa. These 55 deaths were equal to an annual rate of 8·2 per 1000, the zymotic death-rate during the same period being 1·8 in London and 2·1 in Edinburgh. The fatal cases of measles, which had increased in the four preceding weeks from 7 to 43, declined again last week to 34. The deaths referred to whooping-cough, which had been 25 and 16 in the two preceding weeks, further declined to 12 last week. The 3 fatal cases of diphtheria exceeded the number registered in any week since March, 1896. The mortality from scarlet fever and from "fever" showed a decline from that recorded in the preceding week. The 252 deaths in Dublin last week included 47 of infants under one year of age, and 51 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons slightly exceeded the number in the preceding week. Six inquest cases and 1 death from violence were registered; and 72, or more than a fourth, of the deaths occurred in public institutions. The causes of 13, or more than 5 per cent., of the deaths in the city last week were not certified.

WALTON CONVALESCENT HOME, CLEVEDON.—The annual report of the Walton Convalescent Home, Clevedon, has just been issued, and states that 318 patients were admitted during the past year. The balance-sheet shows the receipts to have been £660 and the expenditure £630.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN E. ECKERSLEY has embarked for Sierra Leone. Surgeon-Major E. D. Bringhurst-Farmar is posted for duty in the North-Eastern District. Surgeon-Major T. A. Dixon has proceeded to Strensall Camp for duty. Surgeon-Major S. C. B. Robinson has assumed Medical Charge of the Station Hospital, York, in relieving Surgeon-Major L. W. Swabey.

The under-mentioned officers retire on retired pay:—Brigade-Surgeon-Lieutenant-Colonel William H. Steele and Surgeon-Lieutenant-Colonel Edward O. Reynolds.

INDIA AND THE INDIAN MEDICAL SERVICES.

The under-mentioned officers of the Army Medical Service, on arrival from England, are posted as follows:—Surgeon-Major Stevenson to the Bombay District; Surgeon-Lieutenant Kiddle to the Poona District; and Surgeon-Lieutenant Staddon to the Bombay District. Surgeon-Major Lyons is appointed First Physician to the Jamsetjee Jejeebhoy Hospital, and Surgeon-Major J. P. Barry to act as Civil Surgeon, Belgaum. Surgeon-Captain C. T. Hudson is appointed to act as Civil Surgeon, Thana, pending further orders. Surgeon-Lieutenant Leumann to be on special duty under the orders of the Physician, St. George's Hospital, Bombay, and Surgeon-Lieutenant S. Evans to be on special duty under the orders of the Health Officer of the Port of Bombay. Surgeon-Captain Jones is appointed to act as Deputy Sanitary Commissioner, Central Registration District. Surgeon-Lieutenant W. J. Niblock and J. W. Cornwall to be on special duty at Kurrachee under the orders of the Commissioner in Sind, and Surgeon-Lieutenant W. G. Richard to be on special duty under the orders of Surgeon-Major A. W. F. Street, D.S.O. The services of the under-mentioned officers (Bengal) are placed temporarily at the disposal of the Chief Commissioner of the Central Provinces for employment on famine duty:—Surgeon-Captain W. H. Ogilivie and Surgeon-Lieutenant C. Thomson. Surgeon-Colonel W. S. M. Price, A.M.S., is brought on the Administrative Medical Staff of the Army, vice Surgeon-Colonel W. Graves, transferred to the Home Establishment.

NAVAL MEDICAL SERVICES.

The following appointments are announced:—Fleet-Surgeon William Dudley Wordsworth has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets. Fleet-Surgeon Michael Fitzgerald to the *St. George*. Staff Surgeon Alexander G. P. Gipps to the Medical Charge of the *Malacca* hospital ship.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant A. B. Lyon, M.B., to be Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 1st Hampshire (Southern Division, Royal Artillery): Surgeon-Lieutenant V. J. Blake, M.B., resigns his commission. *Rifle:* 3rd Volunteer Battalion the Royal Fusiliers (City of London Regiment): Surgeon-Lieutenant Arthur Anthony Howell resigns his commission and is appointed Lieutenant. 3rd (Cambridgeshire) Volunteer Battalion the Suffolk Regiment: Surgeon-Lieutenant E. H. Douty, M.B., to be Surgeon-Captain. 5th (Isle of Wight, Princess Beatrice's) Volunteer Battalion the Hampshire Regiment: Victor John Blake, M.B., to be Surgeon-Lieutenant. 1st Volunteer Battalion the South Staffordshire Regiment: Surgeon-Lieutenant W. F. M. Jackson resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement; Henry Spencer Hughes, gent., to be Surgeon-Lieutenant. 1st London: Surgeon-Captain H. F. Stokes to be Surgeon-Major. 3rd London: Surgeon-Major G. Hastings to be Surgeon-Lieutenant-Colonel. 6th Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant George Lyon, M.B., resigns his commission and is appointed Captain.

THE HEALTH OF THE BRITISH TROOPS IN INDIA.

This subject still occupies a prominent place with all interested in the health and well-being of the Army. It is not likely, in the language of the day, "to take a back seat" until the matter has been threshed out and something has been definitely settled in regard to it. There was a large and important gathering at the Royal United Service Institution on the occasion of the reading of Major-General Dashwood's paper, and since that the subject has not been allowed to rest in the House of Commons. The sooner the results of the inquiry into the facts by the departmental committee are published the better. The main points, after all, lie in a nutshell. We have an army of young and inflammable material in India living in a state of celibacy enforced on them for the good of the State. No efforts—that is, no adequate efforts—are made to protect them against themselves or the temptations to which they are exposed, and the consequences are that the amount of venereal disease among them is infinitely greater than it is in all other armies where protective measures are taken. As far as the soldier is concerned everything has been tried in the way of occupation—physical and mental exercises and amusements, institutes, and so forth; but nothing has been done as regards the women with whom soldiers consort, with consequences which, if they continue to increase in the way they are doing, will threaten the safety of the Empire as they surely threaten already to some extent the well-being of the class of society from which our young soldiers are drawn and to which they are supposed to return. Are the opponents of all legislative restrictions on the propagation of disease willing to put their hands in their pockets and pay in taxes the enormous amount that would be required to provide a young married army, even supposing that it would be safe and practicable to do this, which it certainly would not? What, then, do they propose to do? Are they to leave matters as they are, or are they willing to leave them in the hands of those who have an intimate knowledge of India, of the hereditary castes, habits, and customs of its people, and a practical experience of the temptations to which the soldier is exposed and the social and other conditions environing him, as well as some knowledge of what can, and cannot, be done as regards the European military force in that country? It is easy to call every effort that is made to control this class of disease the licensing of vice, but we cannot shut our eyes, except wilfully, to the fact that the sexual appetite is an instinct born in a man with his birth, and that if it were not the dominating one it is the population would certainly not be what it is.

DEATHS IN THE SERVICES.

Surgeon Charles James Fyfe, R.N., on Feb. 18th, in the attack on Benin. He entered the service as surgeon in 1891, and as surgeon of the flagship *Raleigh* served in the naval brigade landed by Rear-Admiral Bedford at Bathurst, on the river Gambia, West Coast of Africa, in February, 1894, in coöperation with two companies of the 1st West India Regiment, for the punishment of Fodi Silah, a rebellious slave-raiding chief. He was mentioned in despatches and received the General Africa Medal, Gambia, 1894, with clasp. As surgeon of the *St. George*, flagship, he served in the punitive expedition against King Koko, of Nimbé, the chief town of Brass on the Niger, in February, 1895. He was also with the naval brigade landed by Rear-Admiral Rawson at Mombasa on Aug. 17th, 1895. He was mentioned in despatches. He was also present at the bombardment of the Sultan of Zanzibar's palace in August, 1896, by Rear-Admiral Rawson's squadron, and was again mentioned in despatches. The death of such a promising officer is to be deeply regretted.

Deputy Surgeon-General Joseph C. Hornsby Wright, on Feb. 26th, at Hampstead, aged sixty-six years. He took part in the Crimean war, served with the Royal Artillery, was present at the battles of Alma, Balaclava, and Inkerman, and at the siege and fall of Sebastopol, and received the medal with four clasps and the Turkish medal. Subsequently he was with the Abyssinian Expedition. He joined the Service in 1852, was promoted to surgeon-major in 1872, brigade-surgeon in 1879, and retired with the rank of honorary deputy surgeon-general in 1880

Surgeon-Lieutenant-Colonel William Andrew Durnford Fasken, at Futtehghurh, North-West Provinces, on Feb. 1st, aged forty-eight years. He joined the Indian Army in 1872, and was promoted to surgeon-lieutenant-colonel in 1892.

MILITIA MEDICAL STAFF CORPS.

The training of the Corps has been fixed as follows:—The Hampshire Company will assemble at Netley on May 1st for sixty-three days' Preliminary Drill, the Annual Training for twenty-seven days to commence on July 3rd. The Middlesex Company will assemble at Woolwich on May 3rd, the Annual Training to commence on July 5th. The Surrey Company

Hosted by Google

and the Eastern Counties Company will assemble for Preliminary Drill on May 3rd, and for Annual Training on July 5th. The Hampshire, Surrey, and Eastern Counties Companies will be placed under canvas, the Middlesex Company being quartered in huts near the Herbert Hospital.

It is announced that new Companies of the Corps will be formed on April 1st, which will furnish six vacancies for fresh commissions.

THE NAVY ESTIMATES.

The Navy Estimates for 1897-98 amount to a net total of £21,838,000, as against £21,823,000 in 1896-97. It is proposed to increase the numbers voted last year by 6300, bringing up the total strength of officers, seamen, boys, coastguard, and Royal Marines to 100,000. The expansion of the fleet has necessitated further additions to various classes of officers. Orders in Council have been obtained authorising increases in various establishments and among these the strength of medical officers has been augmented from 416 to 450. A new arrangement as regards the entry and training of naval cadets will come into force in the present year. It has been decided to gradually raise the age for entering naval cadets by one year and to shorten their course of instruction in the *Britannia* by sixteen months. In future, cadets will be entered three times a year instead of twice, by which 190 cadets will be passed through the *Britannia* yearly instead of 125 as at present.

THE LEE-METFORD BULLET.

The military officials in India have been indefatigable in their endeavours to perfect the Lee-Metford bullet, and according to the accounts received from that country their efforts have been quite successful. It will be remembered that experience in the Chitral expedition showed that the Lee-Metford bullet did not possess sufficient stopping powers. The latest experiments with the new bullet show, however, that it has these and other advantages in addition. A slight alteration at the base of the bullet saves the barrel and gives the rifle a longer life, and in practice at 500 and 1000 yards it gives better target results. Altogether the bullet, as modified and improved in India, is stated to render the Lee-Metford rifle practically about perfect as a weapon.

"WHOLESALE PLUCKING OF MEDICALS."

The *Leeds Mercury* of Feb. 27th, under the above heading, prints the following:—"Out of forty medical students who lately presented themselves for examination for commissions in the Army, only twelve passed the necessary tests for the Army Medical Staff. Evidently the medical schools lack the ability to instruct students up to the present requirements of the service." The *Leeds Mercury* has the facts right, but the deduction is entirely wrong. The plain inference is that the best students do not at present care to compete for commissions in the Service, and that this is the truth every one knows.

THE ARMY MEDICAL SERVICE.

Our Service contemporaries of last week contain articles *apropos* of Mr. Brodrick's speech in connexion with the Army Estimates and his remarks on the Army Medical Service. Mr. Brodrick has told us that the Government has already conceded, or is conceding, several important points, but one which was recommended by Lord Morley's and Lord Camperdown's committees is conspicuous by its absence—viz., the fusion of the Army Medical Staff and Medical Staff Corps into a single corps. We presume that it is the question of military titles for medical officers which bars the way.

THE NIGER EXPEDITION.

There has been some more sharp fighting in Africa, and Ilorin has been captured after a brisk engagement near the Oyon River on Feb. 15th. Major Arnold's column subsequently crossed the river and took Ilorin. Only one British officer was wounded, and the health of the force is understood to be good.

MILITARY NURSES.

A new order of military nurses to be known as the "Army Nursing Reserve," and consisting of a reserve of nurses to supplement the regular nursing service in the Army in time of war, has been approved by the Secretary of State for War.

The following officers are permitted to accept and wear the following decorations conferred by the Khedive of Egypt for services in the recent Dongola Expedition:—Surgeon-Lieutenant-Colonel A. T. Sloggett, A.M.S., the Osmanieh of the Fourth Class, and Surgeon-Captain W. H. Pinches, A.M.S., the Medjidieh of the Fourth Class.

Correspondence.

"Audi alteram partem."

THE VACCINATION PROBLEM.

To the Editors of THE LANCET.

SIRS,—In your leading article of Feb. 27th you insist with much force on the importance of making compulsory re-vaccination an essential plank in any platform that may be constructed for the purpose of influencing Parliament in regard to impending legislation on the subject of vaccination. You also express the opinion that in order to meet the exigencies of the situation "there is but one effective course open, and that is to compensate for indifferent primary vaccination by a system of re-vaccination of children before they cease attending the elementary schools." The second proposition is obviously the necessary complement of the first, for to attempt to make re-vaccination compulsory outside the limits of school age is impracticable. If it cannot be enforced during the period of attendance at school it cannot be enforced at all, except in certain special cases, such as the employés of the State, school teachers, &c. But it may not unreasonably be asked, if we are to impress upon the Legislature the importance of compulsory re-vaccination and are to urge that it shall be made a necessary incident of school life, as is the case in Germany—which we must do if our recommendation is to carry any more weight than that of a mere academic resolution—why should we not urge the identification of primary vaccination also with school life in all cases in which it has not been effectively performed before the child has reached the school doors? From a tactical point of view it will be no more difficult to carry both points than to carry one. The people who will object to the public vaccinator entering the school to vaccinate a child of five years who had not been effectively vaccinated before will object just as strongly to his doing so to re-vaccinate a child of ten. To be content with passing abstract resolutions in favour of universal compulsory re-vaccination is merely to shoot into the air whilst our opponents are levelling their guns at a very definite objective. It has been said that it is not for the medical profession to do more than to express their opinion as to what is theoretically desirable; it must be left to the legislator to give effect to such opinions. Such a course might be very good in Utopia, but we have to deal with a Legislature which will be only influenced by what can be shown to be practicable as well as advisable, and for this purpose we must be prepared to put forward some definite suggestions as to how our views can be carried into effect.

This brings me to the core of the problem with which we have to deal. The Royal Commissioners have *unanimously* reported in favour of meeting in some way the opposition of parents who refuse to have their children vaccinated and who prefer to be fined or to go to prison rather than obey the law. The dissentient minority of two found their recommendation partly upon a disbelief in the efficacy of vaccination, as compared with isolation and other sanitary precautions, and partly upon the alleged injustice, inexpediency, and impracticability of enforcing the vaccination of infants in the teeth of the objection of their parents. The majority of eleven Commissioners, whilst attaching considerable weight to the latter of these two considerations, mainly found their recommendations on *the interests of vaccination itself*, which they consider would be promoted by rescinding the present compulsory clauses of the Vaccination Acts in such a way that, whilst the present undesirable conflicts between the law and recalcitrant parents would be avoided, the withdrawal of children from vaccination through the mere indifference or negligence of their parents would be prevented. In conformity with the opinions which they express as to the value of vaccination the dissentient Commissioners recommend that compulsion in every shape should be abolished, and in so doing they are joined by two of the majority—viz., Messrs. Whitbread and Bright. The nine other Commissioners submit for consideration a scheme which, whilst suggested as a means of meeting what they designate "conscientious objections" only, would, as may be easily shown, lead to wholesale evasion of vaccination. But two of them, Sir Guyer Hunter and Mr. Jonathan Hutchinson, probably seeing that this would be the necessary result of their colleagues' proposals,

Hosted by Google

recommend a modification of the scheme which would greatly lessen the chance of so disastrous a consequence.

Now, I venture to suggest that in this chaos of conflicting opinions, complicated as it is still further by political and other considerations, the lines upon which the supporters of vaccination should proceed are these: (1) to accept loyally the recommendation of the majority of the Commissioners as to the discontinuance of the present mode of enforcing infant vaccination *on the grounds on which it is based by them*—viz., that it is in the interest of vaccination that this should be done; (2) to insist that it is not in the interests of vaccination or of the community that a concession made to wrongheadedness and ignorance, at a period of the child's life when it is difficult to avoid making it, should assume the form of a permanent withdrawal of the child during the whole of its after life from the control which the majority of the Commissioners admit that the State should exercise over all children; (3) that consequently such concession should be made simply in the form of a suspension of the enforcement of vaccination until such time as the operation can be properly and conveniently performed — that is on the commencement by the child of school-life; and (4) that as primary vaccination would thus be associated with the child's entrance into the school re-vaccination should be connected with its arrival at the age when in public elementary schools it would be about to leave.

In a paper which I read before the Society of Medical Officers of Health, to which you refer in your leading article, I endeavoured to show that this scheme is not only one which can be defended as carrying out in spirit the recommendations of the majority of the Commissioners, but that it would offer an opportunity for effecting a reconstruction of the public health service which is urgently needed. I venture to think that if this scheme, which I have elaborated with some detail in the paper referred to, were to meet with the support, not only of those organisations which represent the general opinion of the medical profession, but also that of those members of it who have given special attention to sanitary questions, it would not be difficult to obtain for it the support of boards of guardians, sanitary authorities, and other public bodies throughout the country, and thus to back it up with such a general consensus of opinion as would justify the Local Government Board in giving effect to it in any legislation which they might introduce into Parliament.—I am, Sirs, yours faithfully,

FRANCIS T. BOND, M.D. Lond.,
Gloucester. Hon. Secretary to the Jenner Society.

"THE MIDWIVES REGISTRATION BILL, 1897."

To the Editors of THE LANCET.

SIRS,—I would call attention to the very absurd financial proposals made in Clause 6 of the above Bill. It proposes that, if the income of the Midwives Board, from fees for examination and registration, be not sufficient to pay the expenses of the Board, "the deficiency shall be supplied from the respective local County funds." This proposal could only be made by persons utterly ignorant of taxation, and it converts the whole proposal into a screaming farce; as well might they propose that the expenses of the Board be defrayed out of the Poor-rate. The absurdity of the proposal will be seen if it were suggested that the Governing Bodies of the Solicitors, Chemists, Veterinary Surgeons, &c., were to be kept going by the County rates. I have called the attention of the "County Councils Association" to this great financial blunder and I am now in a position to state that the Parliamentary Committee of that Association has passed a resolution in favour of opposing Clause 6. I have also called the attention of the "Association of Municipal Corporations" to it. Neither has the eminently parochial proposal escaped the Medical Council, because at the meeting of its Executive Committee, on Feb. 22nd last, it has forwarded objections to the Lord President of the Privy Council, in which it is pointed out (*a*) that if the Bill pass, the Medical Council will have to devote part of its time to the business of the Midwives Board: (*b*) that as the funds of the Medical Council are obtained solely from practitioners, it is unfair that such money be used in connexion with the Midwives Board: (*c*) that although the Act does not refer to Ireland and Scotland (?) the money paid by practitioners in these two countries would go to defray part of the expenses of the Board: and (*d*) that the Treasury should make a grant to the Medical Council and to the Board.

I think this suggestion in the Bill that practitioners should not only hand over all their confinements to midwives, but that they should actually help to supply the funds for administering a Midwives Act, is a piece of most sublime impudence, of course the Midwives Association, and the practitioners who back these midwives up, would not dare to make such a proposal to any business men. It would be hooted out of existance. However they think that practitioners have so failed to organize their political influence and power that any gross insult can be offered to us. I have always contended that if we recognise midwives we must also recognise medical Herbalists, and bone-setters. Fortunately events support my contention. In July last (1896) the Medical Herbalists held their annual meeting at Hull, when the President said:—"The law needed to be widened, so as to admit all schools of medical thought." Who can honestly question the accuracy of this President's statement, when he has the action of practitioners connected with the obstetrical Society of London, trading in Midwifery Diplomas? I would wish all success to the Medical Herbalists Association of Great Britain, if the Midwives Bill pass! I wonder why some other medical Society—with a Status similar to that of the Obstetrical, if such can be found—does not start granting diplomas purporting to qualify the holders to practise minor medicine and surgery. Let me tell them there is money in it! From 1872 to 1894 a few practitioners connected with the London Obstetrical Society have *put into their own pockets* about £2324, through the "granting" of diplomas, while a few practitioners in Liverpool have followed suit to the tune of £1435 in 12 years. Now if a few members of "the Godlike Profession" with a high contempt for "filthy lucre," openly "make a ring" in this money-making business, why, I ask in the name of everything fair and equitable, should other poor practitioners not do likewise? A few years ago some simple-minded persons, who were *not* members of "the Christlike Profession," started the "General Council of Safe Medicine Limited" they also following the noble example of the "Christlike" practitioners granted "a few diplomas." Why not? Did we practitioners not set them the example — the noble, honest, aboveboard, and essentially gentlemanly example?

Sirs, the Medical Act 1886 enacts that if any man or woman wish to lawfully practise any part or branch of Physic, such person must (*a*) pass an entrance Examination, (*b*) study for at least (5) five years, (*c*) pass qualifying examinations, and (*d*) be registered. This Act was passed in the sole interest of the Public. Why then do a few practitioners connected with the Obstetrical Society and the Midwives Association wish to repeal this enactment? I would urge that practitioners go on coaching their M.P.'s in the real aims of the instigators of this outrageous Midwives Bill. Certain trading in diplomas has been going on; and it is hoped to make this very questionable trading lawful, by having a Midwives Bill passed. The Medical Herbalists, bonesetters, and midwives are all busily engaged in asking the M.P.'s to vote for this Bill; while constant and persistant lobbying is going on. I am glad to see that at Rochdale and Burnley practitioners have appointed Committees to oppose the Bill. May I suggest that the practitioners in every town and city in the United Kingdom at once Establish local Medico-Ethical Societies for the purpose of defeating this dangerous, degrading, and retrograde Bill. By local organisation all just aims can be accomplished by us. Co-operation with organization—two points too frequently ignored by Practitioners—must prevail. Therefore I urge the immediate formation of Medico-Ethical Societies in every town.

As showing how vigorously the supporters of the Bill are working, I supply the following from the Leicester *Mercury*:—"Mrs. Creighton.—Mrs. Creighton, the wife of the Bishop of London, will preside about the middle of next month over a meeting to be held at London House in support of the Midwives Registration Bill. The promoters of the measure are receiving many assurances of sympathy from all parts of the country." Now, will each practitioner, his wife, and her friends at once ask the wife of their clergyman to write to Mrs. Creighton and ask her to grasp the fact that the existing agencies by which poorer women can be helped in their confinements are more than sufficient, as will be seen on

Hosted by Google

referring to my address on "How are Midwives to be done without," in THE LANCET of Jan. 16th, 1897.

I am, yours etc.,

Liverpool, Feb. 28th, 1897. ROBERT R. RENTOUL.

To the Editors of THE LANCET.

SIRS,—Your correspondent Mr. Watt asks that every confinement may be directly supervised by a medical man. The idea, all must admit, is excellent and much to be desired, but how is it to be carried out? He says, clubs, dispensaries, and the poor-law; but he does not take into account medical men. A large number—I think I may say the greater number—of medical men in established practice would not care to undertake four or five times as much midwifery as they already do: many would not have the time, some would not have the physical endurance necessary, and others from various reasons would feel they were not capable of doing this extra work; and then many—I think very many—would not only be disinclined, but would absolutely refuse, to undertake a large number of midwifery cases. In proof of this assertion I would point to the advertisements of practices for sale. How often we see stated as a special attraction "Very little midwifery," "Hardly any nightwork," or some such expression. We certainly do not want any addition to our ranks to enable us to cope with this new imposition, as we are already far too crowded.

Clubs and dispensaries are well as far as they go, and they might go further with the help of midwives in a manner I have suggested before,[1] without any injury to the public or the profession. Poor-law fees at present are quite inadequate; that, of course, might be remedied, but the machinery is very cumbersome, and, in spite of Mr. Watt's assertion, that "no stigma of pauperism ..... or other social ban attaches to such medical relief," I feel sure he will find many to differ from him who live and practise among the working classes, at any rate in rural districts; the poor do not want to be paupers, neither is it good political economy to encourage them to be. Although the law may allow the guardians to pay anyone for attendance at a confinement, they would, I take it, in actual practice only pay medical men who were not Poor-law officers in cases of emergency. All medical men, I presume, are agreed that the present state of things is too bad to be allowed to continue. The opponents of registration are convinced that there would be danger from want of control and supervision of the proposed midwives, and the promoters of registration are equally certain that medical men cannot possibly do all the work themselves. If only the holders of these two latter opinions could see and admit that there was some truth in their opponents' views the ground would be considerably cleared for useful work and there would be some chance of coming to a definite and useful decision.—I am, Sirs, your obedient servant,

Freshford, March 1st, 1897. CHAS. E. S. FLEMMING.

"SHOULD EPILEPTICS MARRY?"

To the Editors of THE LANCET.

SIRS,—The statements made by Mr. William G. Thistle in THE LANCET of Feb. 27th require immediate and unqualified contradiction. Dr. Gowers is absolutely correct in stating that there is no reason to believe that accidental lesions are transmitted from parents to offspring. Mr. Thistle states that "instances abound in the writings of Darwin, the late Professor Rolleston, and others." Nothing could be further from the truth. Neither of the writers named was able to cite a single well-established instance of such transmission, nor did they profess to do so, except in regard to Brown-Séquard's guinea-pigs, concerning which recent experiment and inquiry have raised considerable doubt. In view of the fact that Mr. Thistle is so completely mistaken as to what is known and accepted on this subject, I am myself unable to attach any value at present to the cases A B, C D, E F, G H, which he states came under his own observation. Mr. Thistle apparently is not aware that a great deal more evidence is required than the mere statements of patients in order to establish such facts as those which he believes in with reference to the transmission of the effects of lesions. If he can satisfactorily establish by a full history and independent testimony any one of the cases cited by him, he will have made a really valuable contribution to science. Hitherto all such supposed cases (to the number of hundreds) have broken down when carefully inquired into.

I am, Sirs, yours faithfully,

Oxford, Feb. 26th, 1897. E. RAY LANKESTER.

To the Editors of THE LANCET.

SIRS,—The cases cited by Mr. Thistle in favour of the hereditary transmissibility of acquisitions are not convincing. Of the four which he gives from his own experience three pertain to the eye, and one of these (Case 3) is useless for purposes of argument. Can we eliminate from the other two the element of coincidence, seeing how numerous are the cases on record in which a parent has lost his sight through accident without any visual defect being transmitted in consequence? Is it not an accepted fact in institutions for the blind that those who have lost their vision through accident, such as small-pox, purulent ophthalmia, and injury, may marry without fear of the defect being transmitted? Apart from the possibility of Mr. Thistle's first two cases being coincidences, is it not also possible that in each of these cases the accident which destroyed the sight of one eye was predisposed to by defective vision in that eye, the defect in the corresponding eye in the offspring being inherited in the usual way? I mention this in order to show how easily error may creep into observations of this kind. Case 4 affords, perhaps, an even better illustration of this. It is highly probable that the deformity of the little finger to which Mr. Thistle refers as having been transmitted from the father to his children is an instance of a well-known deformity which tends to run in families, and that it was not acquired by the father. Deformities of this kind are generally attributed to accident. I am here reminded of a remarkable case which quite recently came under my observation. A medical student damaged his left little finger in football, with the result that it became bent and stiff. Shortly afterwards his father returned from India, and the son noticed exactly the same deformity in his left little finger, and was surprised to hear that it also had been produced by a recent accident. Now, had this accident befallen the father before the son was got, the case would have been cited as an unmistakeable proof of the inheritability of acquisitions.—I am, Sirs, yours faithfully,

Devonshire-street, W., March 1st, 1897. HARRY CAMPBELL.

"A QUESTION FOR ANÆSTHETISTS."

To the Editors of THE LANCET.

SIRS,—The importance of the questions raised by Mr. Clement Lucas in a communication to THE LANCET of Feb. 20th must be recognised by all, both surgeons and anæsthetists alike; but, I think, after a little examination the charges brought against the safety of ether inhalation will be shown to have no substantial basis in fact.

Firstly, as to whether the administration of ether ever causes inflammation of the lungs. During an experience of ten years as an anæsthetist Dr. Hewitt[1] only found two cases in which bronchial irritation followed the use of ether, and only one case, that of an exhausted patient with ovarian tumour, out of twenty-seven reported fatalities for the years 1880–89 inclusive was due to pulmonary congestion. Ether produces an increase of mucous secretion from the respiratory tract; but beyond this in thousands of cases there is neither cough, dyspnœa, nor other symptom of irritation after its inhalation. Now if ether caused lung inflammation at all it surely would be that form we designate catarrhal pneumonia, not due to the pneumococcus, but only secondary to bronchial irritation. Mr. Lucas, however, makes the astonishing suggestion as a second charge that his patient may have been infected with pneumococci by means of the ether inhaler. This is not even a scientific probability, for bacilli do not fly about in a moist atmosphere, but remain adherent to the surfaces upon which they were deposited, and, again, pneumococci are found in the epithelium of the healthy mouth[2] and are therefore present in the respiratory tract in many cases before the ether inhaler is applied. Every inhaling bag, mask, and facepiece should be thoroughly washed, or scalded out if possible, between each case, but with this precaution the addition of the inhaler

subjects the patient to no more risk of lung infection than a ride from Gower-street Station to Portland-road Station on the Metropolitan Railway.—I am, Sirs, yours faithfully,

H. BELLAMY GARDNER,
Assistant Anæsthetist to Charing-cross Hospital.

Welbeck-street, Cavendish-square, W., March 2nd, 1897.

To the Editors of THE LANCET.

SIRS,—Probably other anæsthetists will reply to Mr. Clement Lucas's article "A Question for Anæsthetists," yet I should like to say a word or two on the subject. If the cases of pneumonia after operation which he mentions were due to septic infection from the inhaler, surely the condition of the inhalers must have been filthy in the extreme. At the Middlesex Hospital the interior of the ether bags and face-pieces are carefully cleansed with an antiseptic solution every day after use; but even before that precaution was adopted I never heard of cases such as Mr. Clement Lucas describes, and if they had occurred frequently I imagine that one would not have been left in ignorance on the point. As to the remark about the anæsthetist distending the ether bag with his own breath, I can only say from a pretty large experience in ether administration that in no case whatever can such an objectionable proceeding be necessary.

I am, Sirs, yours faithfully,

THEODORE G. A. BURNS,
Anæsthetist to the Middlesex Hospital.

Welbeck-street, W., Feb. 24th, 1897.

To the Editors of THE LANCET.

SIRS,—We would point out, in answer to the question asked by Mr. Clement Lucas in THE LANCET of Feb. 20th, that it is quite possible to render aseptic all the apparatus for giving ether or gas and ether supplied by us, and that without any difficulty. At the suggestion of Dr. Dudley Buxton we made the rubber portions easily removeable, so that an antiseptic solution can be run into and through them and any like treatment can be applied short of boiling or baking, which, of course, is impossible in the case of rubber. Were there any large demand for such a thing a bag could be devised which could be replaced for every operation, daily or weekly, at a very small cost. We would also point out that it is not necessary for the bag to be inflated by the administrator's breath. If the cone end of our bag is held five or six inches from the mouth a slight blow will fill it, and that not by the administrator's breath, but by the surrounding air. The latest form of chloroform inhaler designed by Dr. Dudley Buxton is made so that the face-piece and all except the rubber parts may be boiled.

We are, Sirs, yours faithfully,

MAYER & MELTZER.

Great Portland-street, W., Feb. 25th, 1897.

"CORONER AND MEDICAL MAN."

To the Editors of THE LANCET.

SIRS,—In your annotation on "Coroner and Medical Man" in THE LANCET of Feb. 27th you lay down very clearly certain points, and I am fully willing to admit my technical error. Nevertheless, I should like to point out that *before I was sworn* I stated that I had had no order to make a post-mortem examination and that from the nature of the case the inquest could not possibly be concluded without the evidence arising from one. Nevertheless, in the face of this the coroner announced his intention not to give such an order. To quote your article, "The coroner, acting within his discretion, thought a post-mortem examination was not called for, and declined to make an order." To think that a post-mortem examination was not called for in the face of my positive statement that no conclusion could be arrived at without was absurd. You do not allude in any way to the other side of the case—namely, what would have happened if I had found some natural cause for death, and so rendered an inquest unnecessary. This was, of course, my reason for making the post-mortem examination, and on my making the remark to the coroner: "If I had found a natural cause of death and so saved the bother and expense of an inquest, you would certainly not have stated that my action was illegal." With this he fully acquiesced. One more question, if I may occupy your space. Is it legal for a coroner to give an order for burial with a certificate of the cause of death without holding an inquest?

I am, Sirs, yours faithfully,

Feb. 27th, 1897. SIDNEY H. SNELL, M.D., B.S. Lond.

THE ETIOLOGY OF BERI-BERI.

To the Editors of THE LANCET.

SIRS,—There has recently been an epidemic of beri-beri at the Richmond Asylum, Dublin. As I take much interest in this disease—almost one-third of all patients I see are suffering from it—and in view of tin poisoning being a possible cause, I should be glad if I could find out through the medium of THE LANCET if there is any possibility of tin-poisoning occurring at the Richmond Asylum. One of the questions which has suggested itself to me is whether the water of the place is conducted through tin-lined pipes. It is probably an acid water, as are many of the waters of this country. I shall be much obliged for an answer to this question, and offer my thanks in anticipation.

I have the honour to be, Sirs, yours faithfully,

J. TERTIUS CLARKE,
Acting Resident Surgeon, Negri Sembilan,
Straits Settlements.

Jan. 28th, 1897.

THE DUBLIN SLAUGHTER-HOUSES.

To the Editors of THE LANCET.

SIRS,—I beg to ask you to allow me to correct an error into which I was led as to the number of slaughter-houses in Dublin. The mistake arose from the numbers having been allowed to remain on the buildings in the order in which licences were granted during the past 100 years. Thus, although these numbers run up to 359 at least, only 66 actually exist at present, in addition to the public abattoir. It is therefore a satisfaction to find that the number actually in use at present has fallen from 87 in 1879 to 66 as seen in the registered list, which has been kindly shown to me by Sir C. Cameron, the chief medical officer of health, and to learn that measures are being taken to extinguish three others. An attempt to abolish others *failed* under the Public Health Act. It is to be hoped that these measures will be continued, although their abolition is attended with expenses.—I am, Sirs, yours faithfully,

Dublin, March 2nd, 1897. CHAS. F. MOORE.

"ALBUMINURIA IN PREGNANCY."

To the Editors of THE LANCET.

SIRS,—I see, to my great regret, that my article on Albuminuria in Pregnancy is published to-day without my revision. The manuscript was written in haste for reading at the Hackney Branch of the British Medical Association on Oct. 5th, 1896, and, as my revised slips will show, stood in need of much amendment. You will remember that when you accepted the paper it was on the understanding that I should be at liberty to alter it freely in slip. The fault, I admit, is mine, as I received the slips at the beginning of the week, but with no intimation that the article would be published that week. Was not the time allowed rather short? In fact I was too much pressed by other work to be able to return it sooner than I did. I hope that you will kindly publish this letter in explanation of a misfortune which has led to the appearance of my article in what I consider—and I fear my friends likewise will consider—to be a very rough and inaccurate state. The corrected slips would reach you on the day of publication.

I am, Sirs, yours truly,

T. CLIFFORD ALLBUTT.

St. Radegund's, Cambridge, Feb. 26th, 1897.

P.S.—In the first paragraph I appear to point to a particular author as a supporter of the mechanical causation. By my revised slips you will observe that such an attribution was not intended.

"AN UNUSUAL RESULT OF ABORTION."

To the Editors of THE LANCET.

SIRS,—In reply to Dr. C. E. Purslow's request for instances of similar experiences made at the end of the account published under the above heading in THE LANCET of

Hosted by Google

Feb. 13th of a case of abortion where the "fœtus contained in its amniotic sac had been expelled" apart from the placenta and the remainder of the membranes, I wish to say that twice in the past seven months I have met with two specimens of a like nature. The first of these I regret to say is not to be had. Through the bursting of the amniotic sac and consequently the loss of the liquor, it was not preserved. The other happily is in existence, and is in the possession of Mr. E. Webster of this place, to whom I presented it. The particulars I met with are, practically speaking, the same as are given by Dr. Purslow. In each instance the fœtus, plainly visible even to the distinguishing of the sex, was enclosed in the intact amniotic sac, the latter being completely free from the presence of any chorionic or placental tissue, which came away separately. In fact the amniotic sac with the fœtus within resembled somewhat the appearance of an egg with the shell off. I should mention, perhaps, that in neither case did I know anything of the pregnancy until I was summoned in attendance, and with regard to the specimen I saved, it was found in and removed from the vagina. Roughly estimating, it was about the size of a goose's egg, and, as far as I could judge, the result of conception of from three and a half to four and a half months' standing. The only difference between Dr. Purslow's description and what I found is in reference to the umbilical cord. This was in my case connected to, and by its weight it caused a dimple to be present on the outer surface of, the sac. No discharge whatever took place previous to the sudden onset of these abortions. I can remember nothing different worthy of notice in connexion with the lost specimen, except that in comparison with the preserved one it was smaller in volume and was found lying in the bed on my arrival.

I am, Sirs, yours faithfully,

R. HILL SHAW, M.B., B.Ch. Dubl.

Brighton, Feb. 18th, 1897.

THE ESSAYS AND ADDRESSES OF THE LATE SIR J. RUSSELL REYNOLDS.

To the Editors of THE LANCET.

SIRS,—We all feel grateful to Lady Reynolds for the publication of these essays, though we have to forego the author's revision. Wanting this, I have to correct the passage in a speech at the University College dinner which refers to the first use of ether at the hospital, where, from a slip of the tongue or of the pen, the name of Mr. Peter Squire is given in place of mine. An old friend writes on Feb. 26th last:—"I perfectly well remember the story of the first anæsthetics from Dr. Reynolds himself, and that he said it was Dr. Squire who administered it." My own recollections of this period were given in the *British Medical Journal* of Oct. 16th, 1896.—I am, Sirs, yours faithfully,

WILLIAM SQUIRE, M.D. St. And., F.R.C.P. Lond.

Ealing, W., March 2nd, 1897.

"ELECTIONS OF MEDICAL OFFICERS OF HEALTH: A PROTEST."

To the Editors of THE LANCET.

SIRS,—In replying to your correspondent, "County Borough M.O.H.," perhaps you will kindly give this an equal prominence to your correspondent's letter. I wish to say that it appears he has yet to learn that abuse is no argument. As to my letter being ill-conditioned, I will leave that matter to others who, judging from his comments, will be more capable of forming a just opinion. I have no doubt in the case of your correspondent it is a question of "a fellow feeling making one wondrous kind." I should have left his communication "severely alone" had there not been some glaring inaccuracies and general misrepresentation in it. If he had given my letter any consideration except to pick holes in it he would have perceived that the point raised was not as to the relative merits of the individual candidate. I may, however, for your correspondent's information say that I have had many years' experience as medical officer of health of an urban sanitary district and was qualified twenty years ago, and that, I dare venture to say, was before he acquired his greatly prized D.P.H. According to your correspondent, anyone who has not the D.P.H. is not to be considered as eligible for a public health appointment. Why not turn out those now in office in large and small districts who have not that diploma? This is the logical sequence of "County Borough M.O.H.'s" argument.

Another argument used by your correspondent shows that he is a special pleader, and is specious but not convincing—viz., that the medical officer of health, in giving up part of his district to the assistant, thereby pays his assistant out of his own pocket. If a man is unable to attend his practice or if anyone cannot do his work through illness or from some other cause, and another man does the work and gets the pay, I fail to see how it comes out of the sick man's pocket. My object in writing to you, whatever your correspondent or others may say, was simply to expose what I considered then and now as an injustice, and I may now say that the members of the Council informed me when the usual process of quizzing was gone through that they did not wish, or, as they expressed it, "the feeling of the Council was against, any man coming into the district to practise." In my application I offered to reside in or near the district. Here what is for the advantage of the district (if a medical officer of health is of any use at all) is considered a barrier. Perhaps your correspondent will say that it is no advantage having the medical officer of health near a wide rural district instead of forty miles off. The fact is, the whole thing when looked at without prejudice may be summed up simply as a farce; and, *pour encourager les autres*, ought to be made known.

Notwithstanding your correspondent's sophistry I retain the *nom de plume*, and beg to remain,

Sirs, yours truly,

March 1st, 1897. JUSTITIA.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Birmingham and the Epidemic of Diphtheria.

THE meeting of Birmingham medical men which was convened at the request of the health committee of the Town Council and held at the Medical Institute on Feb. 25th to discuss the treatment of diphtheria brought out some interesting expressions of opinion. The value of the antitoxin treatment, if taken in hand early and the serum used in sufficient quantities, was strongly insisted upon, Dr. Hill, the medical officer of health, bringing forward the very favourable results obtained from the treatment in post-scarlatinal cases which had occurred in the Scarlet Fever Hospital. Dr. Saundby, President of the Medical Institute, said that it was essential, in the first place, that all cases of diphtheria should be promptly notified, but that, as the absolute diagnosis of diphtheria was impossible in the absence of a bacteriological examination, it was essential also, with a view to obtaining correct statistics, that facilities should be given for a bacteriological diagnosis in each case. He therefore suggested that the proper tubes for obtaining specimens of the morbid secretion should be supplied by the health committee to the medical practitioners making the returns. It was essential that antitoxin should be of good quality and that it should be obtained readily. The serum was an expensive article, and medical practitioners attending the poor could not be expected to supply it at their own cost, while their patients were unable to provide it. He therefore suggested that it would be necessary to supply antitoxin gratis. He also thought that the health committee should arrange for special hospital accommodation for diphtheria, as they had already done for small-pox and scarlet fever. Mr. Alderman Cook, chairman of the health committee, said he understood that the medical profession desired three things—(1) a special diphtheria hospital; (2) an establishment for bacteriological examinations; and (3) an arrangement for the gratis supply of serum. He promised to bring these views before the health committee.

Inquest on a Coroner.

Very rarely does it become necessary to record the death of a medical coroner under circumstances demanding an inquiry of the kind conducted so frequently by himself in his own court. An exceptional instance in the death of Mr. D. R. Wynter, coroner for Central Warwickshire, demands a notice. On Feb. 24th Mr. Wynter, not feeling well, remained in bed; he subsequently sent his housekeeper to a druggist with a prescription for an ounce of prussic acid.

Hosted by Google

Shortly afterwards he was found dead with the bottle half empty by his side. Worries and anxieties of a financial kind were shown to have preyed much upon his mind of late and no doubt disturbed his mental balance. Mr. Wynter had been a Member of the Royal College of Surgeons of England since 1861 and practised at Kenilworth. His manner was always kindly and genial, his public duties were conducted in an exemplary manner, and his friendship was held in esteem by all who knew him. He was unmarried.

March 3rd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester and Salford Sanitary Association.

THE annual meeting of the Manchester and Salford Sanitary Association was held on the 19th ult., Dr. Leech presiding, in the absence of the Lord Mayor. The report showed the existence of serious overcrowding in Manchester, and also that a large proportion of the present dwellings were unfit for human habitation and could not be made so by structural alterations. Some attention was, therefore, given to the question of coöperating with the City Council in their efforts to supply improved dwellings. A good deal of prejudice, fairly to be called ignorant, has existed against the block of workmen's dwellings in Oldham-road, and in consequence of "an outcry" having been raised a deputation visited them and reported "that the arrangements for health and comfort seemed quite satisfactory and that the tenants of the dwellings were invariably satisfied." Opportunities at the various lectures given under the auspices of the association were taken advantage of to combat the prejudices against the so-called "barracks." But more practical coöperation was thought to be needed, and arrangements have been made by the association for a conference on the subject, "which it was hoped might lead to the initiation of some plan for supplementing, by means of private enterprise or otherwise, the provision of dwellings made by the Corporation." The committee were indebted to their colleague Mr. William Thomson for a series of reports on the débris of exploded lamps received from the police through the courtesy of the Chief Constable, and in consequence of the evidence thus obtained they were induced to press upon the Government "the importance of raising the present low flash-point of the mineral oils imported to this country." A conference is also to be held at an early date to discuss the sewage question, which is an important one for Manchester just now. An important event in the past year was the publication of the report of the committee for testing smoke preventing appliances—an offshoot of one of the branches of the association. This report—not a hasty one, for it had taken six years to prepare and embodied an enormous amount of close and accurate work—"demonstrated that the smoke produced by steam-boiler furnaces and in some manufacturing processes might be prevented." The committee therefore had joined other kindred associations in preparing a memorial to the Local Government Board in favour of Government inspection and control of the nuisance. The committee also memorialised the Home Secretary on the subject of carbolic acid poisoning. The association does good work for the community, and might do more to an almost indefinite extent if it were not crippled by want of funds. Manchester is not often charged with want of public spirit, but it is not to its credit that so little is shown towards this association that the income has "dropped to the low sum of £144, which was inadequate to pay ordinary standing expenses." In contemplation of the approaching conferences, &c., an appeal is made for special donations and subscriptions. In moving the adoption of the report Dr. Leech stated that at the present death-rate Manchester and Salford paid a death-toll of 4400 lives more than if the health conditions of Manchester and Salford were equal to the average of those which prevailed generally in England. He spoke of the educational work of the association by lectures and tracts, the special and practical teaching in hygienic matters by the Ladies' Health Society and of the influence it was enabled to bring on various authorities. As regards infectious disease, "of late an advance had been made which placed Manchester in front of almost all, if not of all, other towns." The medical officer of health, Dr. Niven, and Professor Delépine have arranged that in cases of suspected infectious disease "materials were sent to the bacteriological laboratory which enabled a diagnosis to be made at once." The result was communicated to the medical officer of health, and a saving of two or three days often effected in what might be a very serious case. As Professor Delépine said, but for the facilities offered by Owens College it would be necessary for the Corporation to equip and maintain on their own account a bacteriological laboratory.

St. Mary's Hospital: End of the Stanley Grove Scheme.

The annual meeting of the subscribers to the St. Mary's Hospital was held on the 22nd ult., Mr. Duncan Matheson presiding. The most important part of the report related to the negotiations with the Lewis Trustees to establish an amalgamation with the Manchester Southern Hospital, which the trustees made a primary condition for the grant of £70,000. These negotiations have lasted three years, and the Board thinks they have in many respects been needlessly prolonged. "The whole may be briefly summarised as an offer to bestow the gift only on the condition of a transfer of the whole assets of the hospital, which now exceed £100,000, and that the joint hospital should be built in Satnley-grove on land belonging to the Owens College." The Board states that the conditions of the Lewis Trust "involve the abolition of St. Mary's Hospital and the absorption of the whole of its acquired property for the endowment and maintenance of a hospital under the control of the Owens College." It declines to remove the hospital to a site "beyond the sphere of its operations, not only in Salford, but in Hulme, Ancoats, Oldham-road, and many other like districts of congested population, whence the majority of the patients at St. Mary's are supplied." The statement of the financial position shows that in 1895 the total income was £3171 14*s.* 3*d.* and the expenditure was £3899 16*s.* 5*d.*, or a deficiency of £728 2*s.* 2*d.* In 1896 the income was £3245 14*s.* 6*d.* and the expenditure £3901 16*s.* 11*d.*, showing a deficiency of £656 2*s.* 5*d.* The annual deficit thus approaches £700, "which is occasionally relieved by bequests received of less than £500," which, under the by-laws, may be so appropriated. Whatever opinion may be held as to the wisdom of declining to enter into the proposed scheme, there is no doubt as to the desire of the Board to come to a right decision.

The Children's Hospital, Pendlebury.

The sixty-eighth annual meeting of governors was held on the 24th ult., when the need for wider financial support was strongly urged by the Dean of Manchester, who presided.

The Manchester Consumption Hospital.

The annual meeting of supporters of this charity was held the week before last, and as a pleasant contrast to the despondent tone of too many such documents the report showed a sound financial position. This state of affairs warranted the Board in declaring their intentions to bring about some excellent developments in future.

March 2nd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Report of the Police Establishment on the State of Crime in Newcastle-upon-Tyne during the year 1896.

CAPTAIN NICHOLLS, the chief constable of Newcastle-upon-Tyne, has just issued his twenty-eighth annual report showing the amount of crime dealt with during the year 1896. The report shows an increase of drunkenness, particularly among women, accounted for in the opinion of the police by the improved condition of trade. The increase of 15 per cent. in the cases of drunkenness among women accounts to some extent for the large number of children brought before the magistrates on account of their being neglected or ill-treated by their parents. One hundred and nine parents were proceeded against by the police for the ill treatment or neglect of their children; 167, as against 92, children under sixteen years of age, a large majority of whom were considerably under sixteen years of age, were arrested for stealing. Forty-seven children were committed to reformatories, industrial schools, or to the workhouse. Attention, too, is drawn to the very large number of young persons proceeded against for misconduct in the streets, such as gambling and the

Hosted by Google

minor offences of stone-throwing and football. A graceful compliment is paid to Dr. W. D. Arnison and Dr. Beattie for the way in which ambulance instruction has been given by them to the city police. The general health of the police has been good. The report shows a wonderful immunity from serious crime, notwithstanding the increase of drunkenness.

Dr. Arnison.

The rule at the Royal Infirmary at Newcastle-upon-Tyne under which members of the honorary staff have to resign upon reaching the age of sixty years now applies to the senior surgeon, Dr. Arnison, who has tendered his resignation. Dr. Arnison, who has been connected with the institution for upwards of thirty years, has already received the thanks of the committee representing the governors for the valuable services he has rendered to the charity during his long career, and he will be appointed consulting surgeon to the infirmary. Everyone regrets Dr. Arnison's retirement from active duty.

Tynemouth Infirmary.

Mr. Edwards of Corbridge has offered to pay the salary of a resident medical officer at Tynemouth Infirmary for three years if the committee will appoint such an officer, and in addition he will make a donation of £100 to the funds of the institution. At present there is no resident medical officer, and the need of one is much felt. It is proposed to amalgamate the dispensary with the infirmary, and till this is accomplished Mr. Edwards's generous offer is to stand over. There can, however, be little doubt that it will be the means of hastening the amalgamation.

March 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Town Council and the New City Hospital.

AT a special meeting of the Edinburgh Town Council, held last week, the public health committee submitted a report anent the new City Fever Hospital, in which they recommended that accommodation be provided for 600 beds and laid before the council probable estimates of the cost of buildings to accommodate 400, 500, and 600 beds respectively. The estimates ran as follows: For 600 beds, £233 700; for 500 beds, £212,678; and for 400 beds, £181,989. The medical officer of health, the consulting physician, and the medical superintendent of the hospital were all in favour of accommodation being provided for 600 beds. In moving the adoption of the report Bailie Pollard indicated the extent to which demand for accommodation in the hospital had increased during the last few years. Five years ago the average daily number of patients in the hospital had been 150. In the year 1895-96 there had been on an average 302 beds occupied daily, the number ranging from 459 to 250, and he thought the council might be sure that after the new hospital was built the public would be still more ready to send their cases of infectious disease to it for treatment. In seconding the report Mr. Mitchell Thomson argued that, although at present 500 beds might be sufficient for them, it would cost much more in the end if they delayed the erection of part of the hospital. In the discussion that followed there was a considerable difference of opinion as to the size of the proposed hospital. The accommodation provided for fever patients in such towns as Glasgow, Sheffield, Leeds, Manchester, and Dundee was cited as showing that the proposed accommodation in the new hospital was much in excess of what the population in Edinburgh required. Glasgow with its population of 703,000 had 700 fever beds, Manchester with 536,000 of population had 580 beds, Leeds with 402,000 had 400 beds, and in Sheffield, where the inhabitants numbered 350,000, they had only 234 beds; while in Edinburgh, with a population of only 292,000, they proposed erecting accommodation for 600 fever patients. In the end 25 votes were given for 600 beds, and 11 for 500. The recommendation in the report of the public health committee having thus been adopted it was remitted to the public health committee to obtain estimates for the work.

Royal Edinburgh Asylum for the Insane.

The annual meeting of the corporation of this asylum was held in Edinburgh last week, when the managers' report showed a very satisfactory position. After its adoption Dr. Clouston presented his annual report as physician-superintendent. In it he stated that the total number of patients treated in the asylum during the year had been 1354, the average daily number being 901. There had been 115 deaths, 70 of whom were men and 45 women. Dr. Clouston spoke of the limitations that continually met them in their treatment of disease, and showed how the brains of many human beings were doomed, even before birth, as a result of heredity and how a man's brain might be so treated by himself as to bring about pathological changes that could not be recovered from. He spoke of the terrible damage done by an excessive indulgence in alcohol, and stated that during the past year drinking had been the cause of insanity in an unusually large proportion of their cases. He thought that this was possibly due to the fact that the previous winter had been an open one and trade good, and therefore money more plentiful. Dr. Clouston said that the past year had been one of those common since 1890 in which cases of depression of mind were equally frequent with those of morbid elevation of mind. He believed influenza to be the cause of this change of type in mental disease. It had appeared in this country in 1890, and had never since left it. The appearance of this powerful influenza poison in the world was to him the most striking medical fact of his time. He went on to state that the progress of the year had been satisfactory and the health of the patients on the whole good. Speaking of his visit to the East last spring, Dr. Clouston contrasted the treatment of insane patients in the East and at home, saying that an asylum he had seen at Damascus when compared with Craig House was as Hades to Paradise. The Eastern Christian looked on an insane person as one possessed by the devil, and treated him with terrible forms of exorcism. The Mohammedan, on the other hand, looked on insanity as an evidence of special favour from the Almighty, and he was therefore tolerably kind to those thus afflicted.

Medical Lectures at Glasgow.

At a meeting of the Glasgow Philosophical Society on the 1st inst. Dr. Neil Carmichael read a paper on House Sanitation, in which he discussed the circumstances in connexion with the house which influence health, and more especially as these exist in large cities. Dr. Carmichael argued that frequently health was prejudiced by gas filtering through the soil, a condition which could only be met by laying the whole basement with concrete. In connexion with drainage he advocated that all appliances for the removal of waste should be placed in shafts or towers shut off by doors from the house proper. He pointed out that in Glasgow the prevalence of pulmonary tuberculosis was inversely as the cubic space in the house per occupant. This was as distinctly a lesson teaching the need for fresh air as cholera demonstrated the need for pure water. If the lesson were learned with regard to the construction of houses, the arrangements of streets, and the provision of open spaces, the health of the city would be enormously improved. Medical men and sanitary authorities could do something to educate public opinion, but the main responsibility rested upon architects, who practically had the solution of the question in their hands.—At a recent meeting of the Glasgow Dairymen's Association a lecture was delivered by Dr. R. Cowan Lees on Tuberculosis in Relation to Milk-supply.—The free public lectures instituted by the senate of the University of Glasgow continue to realise decided success. On the last occasion Professor John Young, M.D. Edin., was the lecturer, and he attracted a large audience to hear him discourse on the Historical Significance of some of the Coins in the Collection in the Hunterian Museum. The next lecture is by Professor McKendrick, F.R.S., whose subject is to be Sound Waves and the Phonograph.

Glasgow Cancer Hospital.

The annual meeting of subscribers was held on the 25th ult. The medical report was submitted by Dr. Duncan Macartney, and a report on the district nursing by Dr. Robert Jardine. These were adopted. Speeches defining the position and scope of the hospital were made by Dr. Beatson and Dr. Renton. No one doubts that the hospital does good work in relieving many who suffer from cancer in various forms, but the general verdict of the profession is that all this might have been accomplished without the expense of a hospital to enter into competition with the general hospitals, and without the formal organisation of a new hospital staff.

Handsome Gift to the Dundee Royal Infirmary.

Mr. James Key Caird, Dundee, has sent a letter to the directors of the Royal Infirmary offering to provide the necessary sum to build a hospital for the treatment of diseases of women. The full details of the offer have not yet been disclosed, but it is understood that in the first instance a sum of £5000 is placed at the disposal of the directors.

Woodilee Asylum.

In view of the new regulation obtaining in medicine, the Barony Parish Council on appointing two clinical clerks at Woodilee Asylum, Lenzie, have decided to make the appointments open not only to graduates in medicine, but also to fourth and fifth year students, provided always that such students have taken out classes in practical pathology. The clinical clerks will be boarded in the asylum, and will be provided with railway season tickets between Glasgow and Lenzie to allow of their attendance, if they desire it, on special classes in Glasgow. The appointments are to be for six months, three months on the male and female sides alternately. In special cases a three months' appointment may be made.

Aberdeen and the Queen's Diamond Jubilee.

In connexion with a suggestion by Mrs. Ogston, wife of Dr. Alexander Ogston, Professor of Surgery, University of Aberdeen, that children labouring under incurable disease be admitted to Morningfield Hospital — where at present only adult incurables are received — the expense of the maintenance of such children being met independently of the hospital funds, the directors have passed the following resolutions. Children are to be admitted and steps taken to raise funds for the erection and maintenance of a children's wing in commemoration of the sixtieth year of Her Majesty's reign. Meantime, two small wards (with accommodation each for five children's cots) will be furnished and utilised for the purpose. A new wing, containing two wards, accommodating in all twenty children, besides nurses, will cost £2500 to erect, and the annual expense would be £500. It is believed the scheme will be carried out, especially as it is understood that the Thurburn Trust (about to be wound up) will give a substantial contribution. Mrs. Ogston has already received £45 2*s.* 6*d.* in aid of the project.—The managers of Aberdeen General Dispensary in their annual report refer to the necessity for increased accommodation, and suggest as a commemoration of the Diamond Jubilee that a fund might be raised for the enlargement or re-building of the dispensary. A gift of £250 is stated to be in hand to form the nucleus of such a fund. During 1896 10,056 cases were treated and 34,967 prescriptions were dispensed. There was a deficit for the year, which required £400 to be drawn from the general capital.

The late Brigade-Surgeon-Lieutenant-Colonel D. A. Leslie.

The remains of the late Brigade-Surgeon-Lieutenant-Colonel D. A. Leslie, M.D. Aberd., A.M.S., medical officer in charge of the troops at Perth, were interred with military honours on the 1st inst. in Welshill Cemetery, Perth.

(FROM OUR OWN CORRESPONDENTS.)

The Notification of Infectious Diseases Act.

THIS Act, which has been adopted by the corporation of Belfast, came into force on March 1st, and the medical officer of health, Dr. Whitaker, has sent a memorandum to the members of the medical profession explaining very clearly the working of the Act. Many members of the profession think it is rather a pity the corporation adopted the Act before they had done what is absolutely necessary for its being successfully carried out — built a hospital for infectious diseases, as it is impossible really to properly work the Act without having such a place. Never was an infectious hospital more needed than at present, when there is so much zymotic disease in the city—scarlet fever being very prevalent—and when, according to the latest statistics of the Registrar-General for the week ended Feb. 20th, the death-rate had reached the high figure of 30·6 per 1000. At the present time there are only two places available for cases of infectious disease—the Royal Hospital and the Union Hospital. The former institution has only a few fever beds, while the middle and better classes naturally will not go to a union hospital. The corporation decided some time since to build a new infectious hospital, but there would seem to be some extraordinary delay, and up to the present they have not agreed finally on the site.

St. Mark's Ophthalmic Hospital, Dublin.

Mr. R. J. Montgomery, F.R.C.S. Irel., has been appointed assistant surgeon, and Mr. F. Chetwode Crawley, M.B., house surgeon to St. Mark's Ophthalmic Hospital.

The New Hospital for Tyrone.

Arrangements are being made for the holding of a great bazaar next year in connexion with the new hospital in Omagh. The old building there is becoming too small and too antiquated for the demands made on it, and the want of a new building is now being very much felt. It is proposed to inaugurate a committee for the purpose of securing collectors in the different centres in co. Tyrone to raise shilling contributions. The Duke and Duchess of Abercorn, who have granted their patronage for the coming bazaar, are taking the deepest interest in the erection of the new hospital.

Belfast Dispensary Committee.

At the monthly meeting of the Belfast Dispensary Committee, held on March 1st, a letter was read by the secretary from the Local Government Board, enclosing copy of a communication received by them from two members of the committee, who complained of the unpunctuality on the part of the officers of the dispensary station situate at Craven-street, Shankhill-road, Belfast. These two gentlemen alleged that on visiting the dispensary station on the morning of Feb. 8th they found a number of poor people in attendance, but not a member of the staff there except the caretaker. This was shortly after 10 o'clock in the morning, the hour at which the station should open. The first officer appeared at 10.25 A.M., and the others came afterwards. The answer of the officers to the charges was a very complete one. It seems that recently the Registrar-General has (at the suggestion of the Trades' Council) altered the registration hours from 12 to 1 o'clock (on Mondays and Thursdays) and 7 to 8 o'clock (on Saturdays) to 9 to 10 o'clock A.M. and 3 to 4 o'clock P.M. respectively. As a consequence it is quite impossible for the officers to finish their registration duties and be at the dispensary station at ten o'clock in the mornings, the distance from the various places being considerable. After discussing the matter the dispensary committee resolved unanimously that the Local Government Board be informed, in reply to their communication, that the lateness of the hour of attendance of the dispensary officers was due to the time fixed by the Registrar-General for attendance at the registration offices, and request him to change the hour so that it may not clash with the hour for dispensary attendance.

Health of Belfast.

At the monthly meeting of the city council, held on March 1st, it was reported that the health of the city for the past month has been very unsatisfactory, the death-rate being 35·2 per 1000 from all causes, while it was 3·7 from zymotic diseases and 15·9 from chest affections. This terrible mortality from diseases of the respiratory organs is much higher than it has been for a number of years. There is an epidemic of measles and scarlet fever, but the mortality from each is diminishing. The mortality from whooping-cough and typhoid fever still keeps high, and, what is most unusual, eight cases of typhus fever have been reported, with one death. Not for several years has there been a more unhealthy winter than the present in Belfast, and all over the north-eastern part of Ireland there has been an unusual wave of sickness, the mortality of Londonderry being 38·8 per 1000, while further south the death-rate of Dublin has reached the appallingly high figure of 48·3 per 1000.

March 2nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Hygiene of Marriage.

DR. TOULOUSE has just put forward a scheme which greatly exercises the public mind, although it is not absolutely new. He desires to prevent the marriage of

Hosted by Google

persons affected with transmissible disease, or at least to punish those who have deceived their partners by concealing before marriage their taint with any malady making the production of degenerate children possible. Dr. Toulouse is a conjoint director of the Mental Asylum of St. Anne in Paris, and has been lately much to the front on account of his book upon Émile Zola. With the view of making a very complete and detailed inquiry into the physical characters of men of genius Dr. Toulouse commenced with Zola, whose personality is allowed to be remarkable, and published in a large volume the most complete details of the eminent author's constitution. His visual acuity, his various psychical re-actions, and details of his special senses all came in for notice, as did the daily *régime* and mode of life, his cardiac and respiratory tracings, and even the amount of urine he passes daily. This "pipi du génie" has greatly amused Parisians, though Zola is known to have agreed to the inquiry in the interest of psychological physiology, of which science he is a declared partisan. Dr. Toulouse's present idea is that selection should be applied to the choice of partners before marriage with the same care that breeders apply to the choice of animals. To eliminate every chance of the transmission of hereditary physiological taint, he would have epilepsy, mental weakness, cancer, recent syphilis, alcoholism, and tuberculosis regarded as obstacles to marriage. He proposes that every Frenchman shall be provided with a "livret sanitaire" in which the medical attendant should be compelled to inscribe the names of certain diseases if the person in question be affected by them, the list of these diseases to be fixed by a committee of medical men. Dr. Toulouse considers that such declarations could be as legitimately exacted from medical men as those notifying epidemic or contagious disorders. The *livret* in question would be deposited at the prefecture, and in fifty years' time instructive tables of statistics on the laws of heredity could be compiled from them. Until then no one, not even a legal tribunal, would have the right to consult these documents, and a system of key numbers would prevent their comprehension by any non-initiated person. At the expiration of that time the conclusions of so vast an inquiry could be enforced by law, but in the meantime Dr. Toulouse considers that we must prevent by every possible means the marriage of persons affected with diseases known to be transmissible. He would compel intending couples to declare their maladies on pain of divorce should concealment be afterwards discovered to have been practised. As an alternative to divorce a fine might be paid to the non-responsible partner in the case of the birth of a sickly child. If a declaration of ill health be made in the marriage contract, and the marriage is agreed to in spite of it, the law will not attempt to stop the union, for that would be an impossibility; but those who wilfully conceal a morbid taint will be regarded as having committed a breach of trust and will have to make reparation for the damage done. It is generally considered that this scheme is purely Utopian, however much it reflects the legitimate wishes of a learned man desirous to prevent the degeneration of the race, and while such procedure would be a violation of individual rights it would considerably augment the number of illegitimate births.

The Decrease of the Birth-rate.

The question of the decrease in the birth-rate has for some time been a burning one in Paris, and a society has been formed to promote the increase of the population and has held numerous sittings. In all the forthcoming Bills dealing with taxation a diminution of taxation proportional to the number of children in a family is proposed. To do away with the fear which parents have of seeing their fortune divided among a numerous family (for the French law demands an equal division), M. Javal proposes to debit every father with three children at least, so that an only son would succeed to but one-third of the estate and two children to only two-thirds. But in spite of the movement the Malthusian Society still has disciples, and a certain gentleman, noted for his unfortunate attempts at the education of the two sexes in common in a municipal school, has published a pamphlet dealing with methods of checking large families. The "Repopulation" Society has asked that this pamphlet shall be made the subject of a prosecution.

Medical Responsibility.

A medical man of St. Nazaire has just been held responsible for an error in diagnosis. A woman was arrested on a charge of infanticide, and an expert declared that she presented all the signs of recent delivery. Two days later she was delivered of a child which died. She therefore prosecuted the medical man, who was fined 1000 francs, although the *procureur-général* asked the court to acquit him.

The Health of the Army.

The War Minister has published an important report addressed to the President of the Republic upon the Health of the Army. It shows an eminently satisfactory state of matters. In 1896 the death-rate was 5·29 per 1000, the lowest that has ever been observed. This result is due to the steady progress of hygiene. Small-pox is decreasing, and in 1896 there were ninety-seven cases and two deaths. Diphtheria, since the employment of the serum treatment, accounts for only twenty-two deaths per annum. Enteric fever also shows a decrease, although there were 2442 cases with 441 deaths. All the barracks are supplied with spring water filtered through a Pasteur-Chamberland filter, and those places where enteric fever was endemic have become absolutely free since the enforcement of this regulation. The report advises for the future the general use of sterilised water, and sterilisers will be constructed for the supply of water in large quantities. Every army corps will have portable sterilisers, which can be transported to the scene of an outbreak of enteric fever.

A Case of Malingering.

The War Minister, in answering a question put to him in the Chamber relative to the death of a soldier at Marseilles, a death attributed to want of care on the part of the military surgeons, said that the man had brought about his illness on purpose. To get off duty and to be sent to the infirmary he ate six portions of haricot beans; intestinal obstruction and gastro-enteritis supervened, from which he died.

A Terrible Mistake.

Dr. Contjean, the son of the director of the medical school at Besançon, a young medical man well known for his work in biological chemistry, has just died at the age of thirty-two years under very sad circumstances. He suffered from gastric pains, and during the night he got up and taking, as he thought, a packet of bicarbonate of soda poured the contents into a glass of water and swallowed them. The packet contained corrosive sublimate, and he died after terrible suffering.

March 2nd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Alimentation of the Poor.

DR. ANGELO CELLI, professor of hygiene in our University and director of the Gabinetto Igienico at the University Institute, is at work on a series of researches having for their object the improvement of the alimentation of the labouring classes, particularly of the workers in the fields. These latter, or about two-thirds of them, live on the meal of "granturco" (Turkish wheat). Its low nutrient power obliges them to consume it in large quantities, very often bad in quality and rendered still worse by imperfect modes of preparation. The result is seen in their defective physique and, at its worst, in that frightful scourge "pellágra," which, mainly visible in the integument, is also evident in various other lesions, mental alienation included. State medicine has vied with private philanthropic effort to find a substitute for the "granturco," but in vain. It is impossible to combine the two conditions of lower price and superior quality. Professor Celli has set himself to work in another direction to see whether, taking the "granturco" as it exists, its quality and digestibility can be improved without adding to its cost. This result, he thinks, he has attained, at least in one direction—namely, in better grinding processes, from which the meal emerges richer in nitrogenised substances than under the traditional system, while at the same time poorer in husk and indigestible cellulose, and poorer also in fat, which is the chief cause of its rancidity. One defect, however, appeared to neutralise this improvement. Finer and more nutrient, the meal was much less adapted for baking purposes and also

Hosted by Google

for cooking as "polenta" (porridge). Professor Celli, in consequence of this, has sought a remedy in another mode of manipulating the meal. With the coöperation of several skilled members of the baking guild he has succeeded in turning out a paste either from the "granturco" pure and simple or by the admixture of this with the meal of ordinary grain (in the proportion of from 25 to 50 per cent.). Richer in albuminoid substances than the "polenta" of "granturco," richer in the same substances than paste from the other grain even when of the best quality, this composite paste, relatively to nutrient power, is actually cheaper than the aforesaid "polenta." Professor Celli is anxious to have the results of his laboratory findings tested on a grand scale, and will, it is hoped, receive the countenance and support of the Government in the practical extension of his discovery to the alimentation of the poor.

Feb. 28th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Professor Kaposi and the Socialists.

IN the course of a lecture delivered last week Professor Kaposi said that owing to the mildness of the winter only a few cases of phtheiriasis had recently come under his observation, and he added that sufferers from this disease may be found at the meetings which are about to be held in connexion with the Parliamentary elections. These remarks were repeated by the *Arbeiterzeitung*, a journal which circulates among the working classes, and on the evening of the same day some hundreds of Socialists assembled in front of his house and created a disturbance. Next day the newspapers published a statement by Professor Kaposi in which he denied that what he said was capable of an offensive interpretation, and he moreover referred to the gratuitous treatment which he had freely given to necessitous patients for the last thirty years.

Vomiting and Pregnancy.

Dr. Dirmoser has published in the *Medicinische Wochenschrift* an account of twenty cases of hyperemesis gravidarum which he has observed in the course of eight years. There are, according to Lang, three stages of this complaint. In the first stage the symptoms occur at short intervals varying from an hour to five minutes. In the second stage the pulse is accelerated, the temperature is increased, and the urine becomes turbid; patients presenting these symptoms sometimes recover. In the third, which is the comatose or nervous stage, the vomiting decreases, but there are grave cerebral complications; and sometimes strabismus and jaundice. In six cases in which the urine was analysed a great quantity of urobilin was found, as well as hæmoglobin, acetone, peptone, hyalin, and granular tube casts. The presence of urobilin indicates a decomposition of hæmoglobin in the body, and the tube casts point to serious derangement of the kidneys. In three cases Dr. Dirmoser also observed indoxyl and skatoxyl, substances which are products of decomposition in the intestine and are of great significance, indicating a general poisoning of the system and co-existing with increase in the bulk of the liver, spleen, and kidneys. According to Dr. Dirmoser the disease is due to the enlargement of the uterus irritating the motor nerves, as well as the sympathetic and the vagus, both of which when stimulated cause contraction of the stomach. Experiments made by Conteyon have shown that irritation of the vagus increases the secretion of the glands of the mucous membrane of the stomach, promotes the formation of mucus, which neutralises the acid gastric juice, and causes hyperæmia of the stomach. These effects predispose to the formation of toxins, which is further assisted by the atony of the intestine. Dr. Dirmoser accordingly recommends that the stomach should be washed out with a solution of boric acid, that the gases of the stomach should be absorbed by means of powdered charcoal made from the wood of the lime tree, and that food should be given by the rectum. When the patient is eventually able to take food by the mouth it should at first consist of somatose[1] and rice-water.

The Pituitary Body and the Thyroid Gland.

At the last meeting of the Medical Society Dr. Schiff discussed the influence of the pituitary body and the thyroid gland on the metabolism of the tissues. The relation between these two organs has been studied ever since Marie proved that the pituitary body undergoes a change in cases of acromegaly and suggested that it exercises an influence over tissue change. Hypertrophy of the pituitary body has been observed after extirpation of the thyroid gland and in cases of myxœdema. Experiments made by Dr. Schiff with extract of pituitary body show that it leaves the excretion of nitrogen unaltered, but that it increases the excretion of phosphorus, a result indicating the decomposition of a tissue containing phosphorus, which may be either the structures forming the central nervous system, or, on the other hand, the bones. Dr. Schiff considers that it is the bony tissue which is affected. In his investigations of the functions of the thyroid gland Dr. Schiff made four experiments with iodothyrin, and came to the conclusion that its action is by no means identical with that of thyroid extract, a result quite at variance with the opinions of Baumann, who considered that iodothyrin represents, both quantitatively and qualitatively, the efficient part of the gland. Dr. Biedl then referred to the experiments made by him on cats with a view to the investigation of the symptoms which appear after extirpation of the pituitary body. He operated through the mouth, first performing tracheotomy, then partly dividing the velum palati, and finally opening the base of the cranium with a trephine. Sometimes the animals succumbed to hæmorrhage either from a cranial sinus or from the circle of Willis. In one case the animal lived for twenty-four hours, and then died with peculiar spasms similar to those occurring after extirpation of the thyroid gland, and due no doubt to an extravasation into the middle cranial fossa. He confirmed the results obtained by Oliver and Schäfer, who found that the extract of thyroid gland causes a decrease in the blood pressure, whereas the extract of pituitary body, like suprarenal extract, has the effect of increasing the blood pressure.

Accidental Injuries received at the Time of Death.

Dr. Haberda has published in the *Klinische Wochenschrift* a highly interesting case in which a lesion of a necessarily fatal character was sustained at the moment of death. It not unfrequently happens that dying persons receive severe injuries through falling down as they become unconscious. The results of such accidents, of course, vary in extent and severity, ranging from abrasions and bruises on the forehead, the back of the head, the nose, and the knee to fractures of the nasal bones and the extremities, and even to fracture of the skull with extravasation into the cerebral tissue. Dr. Haberda's patient was a woman, aged sixty-five years, who died suddenly. Post-mortem examination showed that the pericardium was fatty and contained about 40 c.c. of turbid blood. The right heart was soft, and on the anterior aspect, close to the anterior longitudinal furrow, there was a longitudinal fissure of the right ventricle. The mitral valves were hard and the posterior aortic valve was thickened; the entrance to the left coronary artery was contracted, but that of the right was normal. The small quantity of blood in the pericardium indicated that the rupture of the heart was not the cause of death, and the absence of suffusion at the place of the rupture proved that it occurred only after the heart's action had ceased.

Thoracic Diagnosis by Means of the Roentgen Rays.

Professor Benedikt has published an account of the observations made by him with the Roentgen rays on a man who suffered from dyspnœa, and who said that two years ago he had an attack of pneumonia and hæmorrhage from the lungs. On the right side in front there was dulness over the apex and bronchial respiration, and there was also dulness of the left back. By means of the Roentgen rays shadows of the heart and the diaphragm were obtained which showed no change in the position of these organs during expiration and inspiration, so that there evidently was an adhesion between the costal pleura and the diaphragm. There was condensation of the lung tissue, and the shadows cast by the lungs were studded with black patches; moreover, an abnormal shadow extending to the axilla corresponded to a situation where there was dulness without any other symptoms, so that no doubt the pleura was thickened and the pneumonia spoken of by the patient had really been pleurisy. The dyspnœa was due to the interference with the action of the diaphragm and to the diminution of the respiratory surface.

Amusing Reply to an Examination Question.

Medical circles in Vienna have been much amused by an

[1] See THE LANCET, Feb. 2nd, 1895, p. 294.

Hosted by Google

answer given by a student who was being examined in pathological anatomy and was asked to name the organs of the body in which cysts most commonly occur. He enumerated several, but omitted to mention the ovary, whereupon the examiner good-naturedly said: "Try to think of an organ which you do not possess," and the candidate, who was of Jewish extraction, immediately replied: "Oh, the prepuce"!

Feb. 28th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Pilgrimages to Mecca.

WE are now well advanced in the Mussulman fasting month of Ramadan, and very soon the devout will be making preparations for the annual pilgrimage so as to be at the holy places before the great feast which will take place this year about April 13th. The French have very properly stopped all idea of pilgrimage from their colonies. The Indian Government seems afraid to take this step, and the Khedive of Egypt can hardly be expected to be more courageous than his English advisers. The Hadj of last year was the largest since 1893, partly because the chief day of the feast fell on a Friday, and the year was therefore considered to be a sacred one; 62,000 pilgrims landed at Jeddah, and the concourse at Mouna was reckoned at 250,000. Jeddah, in spite of its population of 20,000 people, had no money for scavenging purposes, because the Customs revenue destined for sanitation was swallowed up in paying the Government officials, whose salaries were eight months in arrear. The stinks and dangers in the town of Jeddah can be better imagined than described. It is true that the Sultan sent three medical men from Constantinople to inspect, a pasha and two beys, and they reported well of everything they saw. There was no cholera during last year's Hadj, but plenty of small-pox and a corresponding dearth of vaccine, while the other chief diseases were malarial fever, dysentery, and rheumatism, all treated by one sovereign remedy—the actual cautery! One of the greatest wants is a railway from Jeddah towards Mecca. There is apparently no religious difficulty to this, but the amount of backsheesh required by the Bedouins is so enormous that the idea has been reluctantly postponed. One Arab tribe lives during the whole year upon the results of dastardly murders committed by it upon unprotected pilgrims. Nothing can be reformed until the Powers coerce Turkey. Every pilgrim should be provided before landing at Jeddah with a certificate of good health and at least £15 in his pocket. Many now land with less than 15*s.* in their possession, and hundreds are sent back every year by charitable persons. The British Indian pilgrims, I am ashamed to say, are the greatest offenders, about half of them being paupers. The Javanese, on the other hand, are the richest, because Holland insists on every pilgrim possessing an adequate sum. The Persians are universally pitied, because their Consul-General is said to levy very heavy contributions on them. In fact, the pilgrims are robbed everywhere—in Jeddah, *en route* by the Bedouins, and then again at Mecca. The Grand Shereef himself is a famous robber, and among other perquisites receives 8*s.* for each camel hired by the pilgrims. He is not very rich himself by all accounts, because of the large presents he has to send to Turkey. This completes the vicious circle, for it is Turkey which stops all sanitary reform in the Hedjaz, and it is idle to expect that Turkey will ever seriously mend matters there until she is forced to do so by the European Powers. When Europe found herself menaced by plague from Egypt in 1820 she compelled Egypt to create sanitary reforms up to the level of the European knowledge of the day. Has not the time come for Europe to put similar pressure on Turkey and the holy places?

Strongylus Subtilis.

This hitherto unknown worm was discovered at several necropsies in Cairo and Alexandria by Dr. Looss in 1895, and was then reported by him.[1] In the fæcal matter of one of Dr. Sandwith's ankylostomiasis patients, an Egyptian peasant, Dr. Looss has now discovered the eggs of the strongylus subtilis, and this is necessarily the first time that this parasite has been recognised in a living patient. The man now being studied is improving under the ordinary thymol and iron treatment.

Medical Appointments.

Crookshank Pasha, who has been Director-General of the Prisons Department in Egypt since its creation by Mr. Clifford Lloyd in 1884, has now been promoted to the important post of English Controller of the Daira Sanieh. This post carries with it a salary of £2050 a year, and is by far the most lucrative appointment which has yet been given to an English medical man in this country. The Daira Sanieh consists of the personal estate of the Khedive Ismail Pasha, and was reclaimed from him in 1876, at the time of settlement of the national debts. It comprised originally more than 400,000 acres, nearly all being cultivated land, chiefly sugar estates and factories; but to try to reduce the yearly deficit on the revenue several parcels of land have of late years been sold or exchanged to Government servants in lieu of pensions. The Prisons appointment has now been given to the Chief of the Cairo Police. This is, at first sight, a retrograde step, for the weak point of the Egyptian prisons has so far been hygiene and not discipline. It is apparently intended that the future sanitation of the city and provincial prisons shall be regulated by the already deeply pledged sanitary department. Dr. Warnock of the Government Lunatic Asylum and Dr. Wilson, Professor of Physiology at the Medical School, have both had their appointments permanently confirmed. Dr. W. Grant, a son of the late Dr. Grant Bey, has been appointed to the second medical post at Mombasa.

Animal Vaccine Institute.

The statistics for 1896 are very satisfactory. The number of primary vaccinations in Egypt during the year was 17,176 and of these only 577 failed. It must be remembered in addition not only that the vaccinators are all natives, but also that the custom of the country is to vaccinate each child on both its arms. This really means, therefore, a double number of successful results.

Feb. 24th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The National Museum of Hygiene.

WHILE the museum concerns hygiene generally, it has much to do with ships. Here quarters and berths are arranged for the sick on shipboard in models representing several methods. There should be seen in this exhibit a perfect hospital ship—one equipped with all modern conveniences in addition to the best medical and surgical means—as an example for those who construct as well as for those who use. The present sick-bays of warships are altogether inadequate to the exigencies of battle, and berth-decks, or rather makeshifts, could in no manner meet requirements as would properly constructed special hospital ships. These would, indeed, be floating homes of refuge, recognised by all nations as sacred to the unfortunate. In another portion of the building there is a ship-disinfecting apparatus, by the use of which long detention at quarantine is unnecessary, for with it purification is rapidly accomplished in the various parts of the vessel, while all germs contained in the clothing, bedding, &c., of passengers and crew are destroyed by a separate process. In the latter work the possibly infected material is subjected to extreme degrees of heat in closed cylinders, in which are moveable carriers, mounted upon a wheel track used for running material in and out. In fumigating a vessel with the apparatus mentioned two sulphur furnaces are used—one on a tugboat which lies alongside, and the other located on a wharf and mounted upon a track, so that it can be wheeled opposite any part of the ship. Each furnace is provided with a rotary suction blower driven by a steam-engine and connected with the hold of the vessel by galvanised iron pipes. The air is drawn from the hold through one pipe, forced over large pans of burning sulphur, and is driven back through another duct into the hold purified by heat and mixed with sulphur dioxide. While it has been said upon good authority that the best way in which to take wounded men from the hold is to carry them upon the back, effective mechanical arrangements for this purpose

[1] Centralblatt für Bakteriologie und Parasitenkunde, Band xviii., No. 6.

Hosted by Google

have been invented, and the exhibit contains a number of these. The Museum of Hygiene offers a fine opportunity for the medical student in Washington, and many avail themselves of this source of information. Classes from the Naval Medical Department find here much that has to do with the hygienic care of ships and the prevention of epidemic disease.

The Common Communion Cup.

The rector of the Church of the Advent, East Oakland, California, has asked the Board of Health to take such steps as will do away with the common communion cup now used in the celebration of the sacrament. He thinks it is dangerous, and the more since California is a sort of "Mecca" to which phthisical pilgrims from every part of the United States come. "As a result there is a greater percentage of so-called consumptives in the population of California than anywhere else except Colorado. As consumption is now definitely known to be a contagious disease, and as all Christians attend to their religious duties more faithfully when ill than at other times, it follows that there is a particular need of safeguards in this State about the common cup in the communion service. May your petitioner presume to ask which member of your board would be willing to sip from a cup from which fifty strange persons had drunk, some of whom were known to be affected with phthisis pulmonalis?"

"Sweat Shops" in High Places.

According to recent investigation by the factory inspectors some of the most fashionable millinery and dressmaking establishments in New York City are quite as veritable "sweat shops" as are to be found in the tenement districts of the east side, where clothing is made by wretchedly underpaid workers huddled together in the most narrow and unwholesome quarters. The following is a summary of some of the worst cases. On Fifth-avenue the inspector found twenty-five girls working in a cramped room which would hold only nine if due regard to health and comfort were paid. In another fashionable place the space adapted to eighteen girls actually held twenty-eight. In a dressmaking establishment twenty-seven were found working where there should have been but thirteen. Miss Cane, the inspector, says that insanitary crowding is general among the fashionable establishments. The lower floors are usually spacious, with luxurious furnishings. The upper floors, where the girls work from early morning until midnight, are cramped and crowded in as direct a violation of the State laws as any place discovered in the poorer class of tenement houses.

A Training School for Coloured Women.

The scheme of the New Orleans University Medical College to found a training school for coloured women as nurses is well under way and is assured of success. The aim is to supply at moderate rates nurses who will be competent for all the duties performed by white nurses and willing and able also to relieve the strain put upon an ordinary household by sickness, instead of, as is now sometimes the case, aggravating it. Careful inquiry was made by the physicians interested in the movement to make sure that there would be a paying demand for the graduates of the school, and the result was satisfactory. No one who has had much experience with sickness is ignorant of the fact that the trained nurse of to-day is, though indispensable, extremely expensive, directly and indirectly, or that there may be many cases in which less costly, even if less accomplished, attendants would be a great convenience. If coloured girls can be trained to meet this need—and they unquestionably can—it will open to their race an occupation which those fitted by intelligence and character now entirely lack.

Semi-centennial Anniversary of the Academy of Medicine.

The semi-centennial anniversary of the New York Academy of Medicine occurred on Jan. 29th. An audience of upwards of 3000 citizens assembled in Carnegie Hall, and among the distinguished persons on the stage was the President of the United States. Of the 150 physicians who assisted in the organisation of the Academy fifty years ago only eight are still living. Dr. Lewis A. Sayre, one of the incorporators, was present and addressed the meeting. Dr. Purple, a former President and an original member, gave a history of the growth of the Academy and especially of its library, which is now second only to the library of the Surgeon-General at Washington. The ceremonies were concluded with an address by the President of the United States on "The Physician as a Citizen." After alluding to the evils of unrestricted charlatanism he remarked: "I need not suggest that such evils are allowed to exist by reason of the insufficiency of our laws or a laxity in their execution. I have intimated that for this condition you are not responsible in a professional sense; but are you sure that as citizens you are doing all in your power to remedy the situation? We cannot but think that the discoveries and improvements in the medical practice which we now enjoy are dearly bought if the members of the profession in their onward march have left behind them their sense of civic obligation and their interest in the general public welfare. We cannot accuse you of utter neglect of your duty to the country; and yet we cannot keep out of mind the suspicion that if your professional work in exposing evils were more thoroughly supplemented by labour in the field of citizenship these evils would be more speedily corrected. If laws are needed to abolish abuses which your professional investigations have unearthed, your fraternity should not be strangers to the agencies which make the laws. If enactments already in force are neglected or badly executed, you should not forget that it is your privilege and duty to insist upon their vigorous and honest enforcement. If members of your profession were oftener found in our national and State legislative assemblies ready to advocate the reformatory measures you have demonstrated to be necessary and to defend your brotherhood against flippant and sneering charges of impracticability, the prospect of your bestowal upon your fellow-men of the ripened results of your professional labour would be brighter and nearer. You will, I hope, permit me, in conclusion, to enjoin upon you the duty of an active and general interest and participation in public affairs for the promotion of your country's good in all its phases. No object of personal ambition and no activity of professional life should be permitted to withhold from our Government the tithe of devotion and service due from its thoughtful, intelligent, and educated citizens."

Feb. 20th.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates passed in the under-mentioned subjects in February:—

Surgery.—J. T. Brickwell, Guy's Hospital; E. C. Corfield, St. Bartholomew's Hospital; C. E. Covernton, Guy's Hospital; C. I. Ellis, Aberdeen and St. Thomas's Hospital; H. Fulton, Guy's Hospital; F. Harvey, St. Bartholomew's Hospital; H. Lewkowitsch, Breslau; H. H. Mouckton, King's College; C. W. Moore, Manchester; A. W. Oxford, Charing-cross Hospital; F. M. Simmonds, Edinburgh; E. G. Smith, Westminster and London; and S. K. Vines, Birmingham.

Medicine, Forensic Medicine, and Midwifery.—G. W. Dutton, Middlesex Hospital; R. B. Greaves, Sheffield; J. L. F. De Gannes, University College; F. Harvey, St. Bartholomew's Hospital; G. E. H. Sargent, London; and S. F. Smith and L. W. Seymour, St. George's Hospital.

Medicine and Forensic Medicine.—H. R. Rice, Birmingham and London.

Medicine.—P. H. Collingwood, St. Thomas's Hospital; T. Jones, Middlesex Hospital; C. W. Moore, Manchester; A. P. Mürtz, King's College; and F. M. Simmonds, Edinburgh.

Forensic Medicine.—E. P. Hewitt, St. Mary's Hospital; and J. P. Race, Manchester.

Midwifery.—F. Adams, St. Thomas's Hospital; A. H. Grace, Bristol; and M. Sharp, Royal Free Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery: Messrs. Dutton, Fulton, Grace, Harvey, Hewitt, Mürtz, Oxford, Race, Sargent, S. F. Smith, and Miss Sharp.

ROYAL WEST OF ENGLAND SANATORIUM, WESTON-SUPER-MARE.—The annual meeting of the Royal West of England Sanatorium, Weston-super-Mare, was held on Feb. 13th, under the presidency of Sir C. D. Cave. The honorary secretary in his report stated that the receipts were £3016, which with a balance brought forward from 1895 of £601 made a total of £3617, as against £3415 the previous year. The expenditure was £2950, as against £2814 in 1895. The number of convalescents admitted had been 1441—viz., 782 men and 659 women; last year 1391 had been admitted (643 men and 748 women). The hot and cold sea water baths still continue to afford invaluable benefit to many convalescents. The number of baths taken during last year was 5078, the number in 1895 being 4198. The report adds that these baths are of immense importance to the institution.

FOREIGN UNIVERSITY INTELLIGENCE.—*Rouen:* Dr. Albert Martin has been appointed Professor of Clinical Midwifery.—*Heidelberg:* Dr. Karl Kaiser has been appointed Extraordinary Professor of Physiology.

CLEVEDON COTTAGE HOSPITAL.—In the recently issued report of the Clevedon Cottage Hospital it is stated that a larger number of patients were received at the hospital during the past year than during any preceding year. There were 91 cases admitted, and 55 were discharged as recovered, 20 as improved, 3 as no better, 2 were removed, 1 died, and 10 remain. The receipts from all sources were £446, payments were made to the extent of £420, and a balance of £26 remains.

ABERYSTWITH INFIRMARY AND CARDIGANSHIRE GENERAL HOSPITAL.—The annual meeting of the subscribers of the Aberystwith Infirmary and Cardiganshire General Hospital was held on Feb. 6th, under the presideney of Mr. H. C. Fryer. The report showed that 183 patients had been admitted during the year, as against 175 in 1895. There had also been 1449 out-patients, being a decrease of 67 from the previous year. There was an adverse balance at the end of the year of about £12. Mr. J. G. W. Bensall was elected President.

CRIME IN NEWPORT (MON.).—The annual report of the head constable of Newport (Mon.) shows that the number of indictable offences reported to the police during 1896 were 355, for which 293 persons were apprehended or summoned—viz., 230 males and 63 females. This showed a decrease of 80 offences reported and 23 persons arrested or summoned as compared with 1895. Of the 293 persons proceeded against, 270 were tried summarily, 8 were discharged on withdrawal of prosecution, 4 were discharged on the evidence, and 11 were committed for trial.

MUNIFICENT BEQUESTS.—Mrs. Worthington, widow of the late Mr. William Henry Worthington, head of the well-known firm of brewers, who died last week, has left her residence, Derwent Bank, Derby, to the Derbyshire Infirmary for the purpose of a convalescent home. Should the infirmary authorities deem the mansion unsuitable they are empowered to sell it and benefit the institution to the amount of £10,000. There are other bequests for charitable purposes amounting in the aggregate to £50,000.

LISKEARD COTTAGE HOSPITAL.—The first annual meeting of the Liskeard (Cornwall) Cottage Hospital was held on Feb. 18th. The report stated that from April 28th, 1896 (when the building was opened by Mrs. Passmore Edwards), to the end of the year fifty-four patients had been admitted and eighteen out-patients had been treated. The total expenditure had been £543 and the receipts £615, leaving a balance of £72 in hand. The receipts include a cheque for £200 from Mr. Passmore Edwards towards furnishing the hospital, the total cost of which, including the dispensary, amounted to £320. Mr. Edwards was re-elected patron.

ROYAL UNITED HOSPITAL, BATH.—On Feb. 16th the Earl and Countess of Cork assisted at the opening of a bazaar which has been organised at Bath for the benefit of the Royal United Hospital. The funded income of the hospital is £500, and at the close of 1896, notwithstanding the receipt during the year of legacies amounting to over £2000, there was an adverse balance of £1245. The present hospital was opened in 1826. A new wing was added in 1865, and more recently a children's ward has been provided. Better accommodation for the nursing staff and a new kitchen are urgently required, and so it was decided to hold this bazaar, by which it is hoped to raise a sum of at least £1500.

HEALTH OF TAUNTON.—Dr. H. J. Alford, the medical officer of health for the urban and rural districts of Taunton, in his annual report for 1896, states that in the urban district the birth-rate was 31·9 per 1000, the death-rate 16·9 per 1000, the zymotic death-rate 3·5 per 1000, and the infant mortality 145 per 1000 births. The health of the town during 1896 was remarkably good, and had it not been for an epidemic of measles, which caused a heavy mortality, the year would have compared most favourably with its predecessors. In the rural district the birth-rate was 29 per 1000, the death-rate 14·2 per 1000, the zymotic death-rate 1·04 per 1000, and the infant mortality 79·5 per 1000 births. The number of cases admitted to the sanitary hospital during the year was 65.

IT is arranged that the tenth annual Cookery and Food Exhibition shall be held from May 12th to May 19th at the Niagara Hall, St. James's-park. Further particulars respecting the exhibition may be obtained from the honorary secretary, 329, Vauxhall-bridge-road, S.W.

PRESENTATION TO A MEDICAL MAN.—On Feb. 18th a handsome walking-stick was presented to Mr. John Howard-Jones, M.B., C.M., D.Sc. Ed., by the ambulance class of the Newport (Mon.) borough police force, as a mark of appreciation for his services as honorary lecturer of the St. John Ambulance Class.

SALISBURY INFIRMARY.—The half-yearly statement of the receipts and expenses of the Salisbury Infirmary has just been issued. The total receipts, including church collections £756, subscriptions £922, donations and legacies £522, made a total of £3422, and the expenditure amounted to £4006, leaving a balance of £584 due to the treasurer.

WILTSHIRE COUNTY ASYLUM.—The visiting committee of the Wiltshire County Asylum have decided on the erection of a new boiler house and other additions connected with the provision of steam for heating, cooking, &c., and to raise by loan for such purpose and for the installation of electric lighting at the asylum a sum of £5000 in addition to the loans previously sanctioned by the county council.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—The annual meeting of the subscribers to Weston-super-Mare Hospital and Dispensary was held on Feb. 15th. The report showed that 341 patients had been admitted and that 602 out-patients had been treated. The casualties relieved were 881. The dispensary now has 2650 members entitled to claim its benefits. The expenditure slightly exceeded the income, the year beginning with a surplus of £27 and ending with a deficit of £4.

ROYAL PORTSMOUTH HOSPITAL.—At the annual meeting of the Portsmouth Hospital, held on Feb. 23rd, plans were presented of a new hospital which it is hoped will ultimately be built on the present site. This will be done gradually. In commemoration of the sixtieth year of Her Majesty's reign it is proposed to erect two new pavilions, each to contain forty beds. Miss Weston, "the sailors' friend," who has recently been an inmate of the hospital after a serious bicycle accident, has contributed through Mr. Rundle, F.R.C.S. Eng., £100 to the building fund, which now amounts to over £6500.

FOOTBALL CASUALTIES.—In a match played between Clifton and Bridgwater Albions on Feb. 20th, at Bristol, a member of the former team dislocated his knee.—On the same day, during a match between Middlesbrough and Stockton Corporation Officials, one of the players fractured his clavicle.—In a match on Jan. 30th last, between the Star Athletic and Homerton Clubs, a player, a youth of Bromley-by-Bow, aged fifteen years, received a blow on the head, from the effects of which he gradually became worse, and died last week from exhaustion.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A clinical meeting of this society was held at Stanley's, Lavender-hill, on Feb 10th, Dr. Benjamin Duke being in the chair. Mr. John Gay showed a Skiagram of a case of Fracture about the Elbow in a Child. Mr. J. B. Howell showed a Fœtus with Spina Bifida. Mr. A. E. Dodson read short notes on the following: (*a*) a case of Spina Bifida; (*b*) a case of Unusually Slow Pulse; and (*c*) a case of removal of Foreign Body from the Ear. Mr. T. A. I. Howell read short notes on a case of Vaccination with Rare Complications.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES.—The annual meeting of the Manchester and Salford Hospital for Skin Diseases was held recently, the Mayor of Salford presiding. The report stated that the number of new out-patients for the past year was 3271 against 3504 for 1895. The committee attributed this decrease of 233 to a considerable extent to a more careful and regular inquiry as to the claims of certain applicants to be afforded charitable relief. Owing to want of funds the in-patient department was small, but had proved to be of great benefit since it was established eighteen months previously. During the year forty-four patients were taken in for treatment. The subscriptions during the year had increased by nearly £100, but the balance-sheet of the year showed a deficit of £330.

Hosted by Google

NORTH OF ENGLAND CHILDREN'S SANATORIUM.—The annual meeting of subscribers to the North of England Children's Sanatorium was held recently at the institution, Southport, under the presidency of the Mayor, Mr. G. H. Pollard, M.D. Edin. The report showed that 842 children had been inmates during the year, 335 of whom had been sent by the governors of the Cotton Districts Convalescent Fund. The amount received from the children was £937. A recent rule, by which a cot can be appropriated for one year by a donation of fifteen guineas, was becoming much appreciated, nearly £240 having been received on this account.

MIDDLESEX HOSPITAL.—The annual general court of governors of the Middlesex Hospital was held in the board room on Feb. 25th. Mr. Custance (the secretary of the Hospital Sunday Fund) presided, and amongst those present were the Right Hon. Sir Ralph Thompson, K.C.B., Mr. Francis Hoare and Mr. G. J. Marjoribanks (the treasurers), Colonel the Hon. Herbert Eaton, Sir Arthur Townley Watson, Dr. Cayley, Dr. Coupland, and other governors to the number of thirty. The report for the year 1896 spoke feelingly of the great movement set on foot by H.R.H. the Prince of Wales in support of the hospitals, and after dealing with the year's working of the hospital gave some details of the new convalescent home which had recently been opened at Clacton-on-Sea, from which it was to be gathered that there was still the sum of £28,000 to be collected to free this home from debt. During 1896 there were 3598 in-patients, whose average stay in hospital was about twenty-nine days, and among whom there were 355 deaths; there were also 44,484 out-patients treated, whilst 393 patients were sent to convalescent homes. The report also alluded to the satisfactory manner in which the newly constituted Medical School Council was performing its functions. Dr. Coupland, who has held the office of Dean for four years, has resigned that post, and has taken his place as an elective member of the Council. Dr. William Pasteur has accepted the office of Dean, for which he is well qualified by his services as secretary to the Medical School Committee. After the conclusion of the formal business Dr. Cayley, the senior physician, proposed that Dr. Cecil Yates Biss, who had been connected with the hospital for sixteen years, should be granted the title of Physician to Out-patients, which was duly conferred upon him. We understand that H.R.H. Princess Christian has consented to lay the foundation-stone of the New Cancer Wing of the hospital on July 1st next.

COMPLAINTS AGAINST AN ISOLATION HOSPITAL.—Prolonged inquiries by the Guildford, Godalming, and Woking joint hospital board have been held during the last month or two into complaints made by the father of a child who was admitted for scarlet fever. While recovering in the hospital she was accidentally burnt owing to her clothes catching fire through the bars of the fireguard. The father complained and a strict investigation was made, the medical men appearing to agree that the injuries were severe though fortunately not of a permanent nature. Further, the father complained that the child's head was dirty on her discharge. The child was six weeks in the hospital and was reported as "clean" on admission. As to this matter the committee reported that "it is clear that the precautions taken by the staff of the hospital to prevent the transmission of parasites from head to head cannot be said to have been satisfactory." As to a complaint that it was some hours before the child received medical attendance, the committee explained that this arose from the absence of the superintendent and a nurse. On the latter's return the girl was temporarily attended to. The medical man arrived three hours later. As to a complaint of shortness of food, the committee thought this charge unfounded, but said the method of distribution needed amendment. Further, the parents were assured that the case was a slight one; the committee had ascertained that for some days it caused the whole staff much anxiety. Finally, the committee agree that the whole question of the administration of the hospital requires consideration with a view to reform and improvement, and are of the opinion that fuller inquiries should have been made earlier, such inquiries being prevented by a request from the mother that the neglect of one of the staff at the time of the accident might be forgiven. The board are considering the question of reform in committee.

LITERARY INTELLIGENCE.—Messrs. J. & A. Churchill will shortly issue a small work on "Antiseptic Principles for Nurses," by Mr. C. E. Richmond; and "Deformities of the Fingers and Toes," by Mr. William Anderson, surgeon to St. Thomas's Hospital. Also the following new editions: The fifth edition of Dr. Waring's "Bazaar Medicines," revised by Dr. Aitchison; the fourth edition of Tomes's "System of Dental Surgery," with forty new illustrations; and the seventh edition of "Mechanical Dentistry," considerably enlarged by the author, Mr. Joseph Richardson.

UNIVERSITY OF CAMBRIDGE.—Two reports on degrees for women students have been laid before the Senate. One signed by nine members of the Syndicate advocates the grant of the titles of B.A., M.A., D.Sc., and D. Litt., but no medical or divinity degree, to women who take honours in a Final Tripos Examination after the periods of residence in Cambridge required in the case of men. The other, or minority report, signed by five members, while conceding that it may be desirable to grant an academic title to duly qualified women, whether they have resided in Cambridge or not, proposes that the degree should be a new one, like M.Litt. or M.Sc., which would not suggest membership of the University, with its accompanying privileges in regard to government. The majority report rejects an application from the Royal Holloway College that its students may be deemed eligible for titular degrees. The reports will come before the Senate for discussion on Saturday, March 13th. On Feb. 25th the degrees of Bachelor of Medicine and Bachelor of Surgery were conferred on G. E. Hadow, M.A., Caius; L. B. Rawling, B.A., Caius; and H. W. P. Young, B.A., Caius. Dr. A. W. Williamson, F.R.S., Emeritus Professor of University College, London, has been appointed an Elector to the Chairs of Chemistry and Organic Chemistry (Jacksonian), now held by Professor Liveing and Professor Dewar respectively.

DIPHTHERIA IN LONDON.—Fatal diphtheria showed a most decided rise in London last week as compared with earlier weeks, the deaths registered having been 62, as compared with 46, 37, and 40 in the preceding three weeks. The 62 deaths were 27 in excess of the corrected decennial average for the eighth week of the period 1887-96. Islington and Shoreditch were each credited with 6 deaths, Lambeth and St. Pancras each with 5 deaths, and Poplar, Camberwell, and Lewisham sanitary areas respectively with 4 deaths. The admissions to hospital in the week were 102, against 95, 104, and 104 in earlier weeks, and last Saturday there were 855 patients suffering from the disease under isolation. All the 62 deaths were of young persons aged under twenty years. In the Outer Ring there were 7 deaths registered, 4 of which belonged to the West Ham registration district.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Summer Clothing for the Metropolitan Police.

THE Home Secretary has communicated to those who have been taking an interest in the matter that arrangements have at last been made for the issue of light clothing to the Metropolitan Police for use in the summer months.

Verminous Persons Bill.

A Bill with this title is now before the House of Commons. It was introduced on Monday, March 1st, and its purpose is to permit local authorities to provide cleansing and disinfection for persons infested with vermin.

The Whipping of Prisoners.

Mr. Joseph Pease has introduced into the House of Commons a short Bill "to prohibit the personal correction of prisoners." The Bill is down for second reading upon Tuesday, March 30th.

HOUSE OF COMMONS.

THURSDAY, FEB. 25TH.

The Oyster Question.

Mr. Henniker Heaton asked the President of the Board of Trade whether he was aware that, owing to the publication by the Local Government Board of a report on cholera and of another report on oyster culture in relation to disease, public confidence in the wholesomeness of oysters had been so much impaired that the annual consumption of oysters had fallen off to the extent of three-fourths and a large number of the fishing population had been reduced to distress;

Hosted by Google

whether he had observed that the reports alluded to condemn only a few small oyster layings round the coasts of England, while many of the chief layings, including the whole of those on the coast of Kent, were declared free from contamination; whether he was aware that the Kentish layings thus pronounced free from disease were more extensive than all those in the rest of the kingdom put together; and whether he was aware that they had suffered from the lack of demand equally with the polluted layings; whether, with a view to restore public confidence in a valuable article of diet and assist the fishing population, he would recommend the appointment of inspectors of layings, and also of all shops and stalls for the sale of oysters, authorised to enforce such conditions of sanitation as might effectually safeguard the public against disease; whether he was aware that foreign oysters were frequently introduced into this country from polluted layings, and that the only instance of enteric fever in an epidemic form arising in England from oysters was traced to the eating of Dutch oysters; and whether he would, therefore, recommend that it should be made a penal offence to sell oysters brought from foreign layings without declaring their origin at the time of sale and without plainly marking such origin.—Mr. Ritchie replied: I have little doubt that the reports referred to have, to some extent, impaired the confidence of the public in the wholesomeness of oysters, but I venture to think that my hon. friend over-estimates the decrease in their consumption. I am aware that whilst only a certain number of beds are condemned others have suffered from the reduction in demand. The trade has brought the matter to the notice of the President of the Local Government Board, whose province it is to deal with questions affecting the public health; but if it should be found that the Board of Trade can take any useful action in the matter I shall be ready to give careful consideration to any proposals which may be laid before me. As at present advised, I do not think that the marking of foreign oysters would be either feasible or an efficient remedy.

Vaccination in Ireland.

Mr. Gerald Balfour, replying to a question by Mr. Pinkerton, said the Local Government Board in Ireland have power to issue any regulations they think fit to prevent the spread of dangerous infectious diseases such as small-pox, and thus to compel compliance with the vaccination laws. No boards of guardians in Ireland have refused to do their duty in this respect.

Venereal Disease among the Troops in India.

Lord George Hamilton, questioned by Mr. Cameron as to the terms of the reference to the departmental committee on this subject and the intended action of the Government, made the following statement, viz.:—The terms of reference were as follows: To examine the official returns of venereal disease among British troops stationed in India and to report what changes, if any, have taken place during recent years in the prevalence of such disease and in its character and intensity; also, to obtain and report any information which may be available with regard to the presence of venereal disease and its character and intensity among foreign armies. The report is now under my consideration and will be published. The evidence on which it is founded, being almost entirely documentary, has not been separately recorded, but is embodied or referred to in the report. I am at present unable to say what course may be taken by Her Majesty's Government; but undoubtedly the House will have an opportunity of discussing any decision we may arrive at.

FRIDAY, FEB. 26TH.

The London Water Question.

At the commencement of this sitting the Bill of the East London Water Company was read a second time. Mr. Sydney Buxton took the opportunity of saying that he did not intend to oppose the Bill in any way, because it was essential that the company should have the powers they sought to carry out the projected works. But he felt constrained to express the regret which he believed the ratepayers of London felt that the question of the water-supply of the metropolis was being dealt with piecemeal, thus involving great additional trouble and expense. It had been understood that the Government were prepared to deal with the whole question last session, and that not having done so they would have introduced a Bill this session. But it was evident that they did not intend to legislate on the matter. After the motion for the second reading had been agreed to it was decided to instruct the committee to whom the Bill is referred to insert such provisions as will insure the acquisition by the local authority of such a suitable area of open space as in the judgment of the committee ought fairly to be substituted for the common rights proposed to be extinguished under the Bill. These common rights are over land in the neighbourhood of Tottenham, where the company propose to construct a new storage reservoir.

MONDAY, MARCH 1ST.

The Stamping Out of Rabies.

Mr. Bigwood asked the President of the Board of Agriculture whether his department was now prepared to adopt the recommendation of the departmental committee and make a determined effort to stamp out rabies by exercising directly the powers which they already possess under the Diseases of Animals Act.—Mr. Walter Long replied: There appears to me to be great force in the recommendations of the committee, and I am now engaged in the consideration of some of the practical questions which the adoption of those recommendations involves. I hope to be in a position to make some further announcement on the subject at no distant date.

Food Adulteration.

Mr. Kilbride asked the President of the Local Government Board whether a Bill dealing with the adulteration of food would be introduced this session by the Government, and, if so, when; and whether the Bill would embody the recommendations of the committee which considered the question of food adulteration, or whether it would deal with an amendment to the Food and Drugs Act as distinct from the Margarine Act.—Mr. Chaplin said that the question whether a Bill would be introduced in the present session on this subject must depend on the progress made with other Government Bills. The Bill which had been prepared dealt with the subject as a whole, and it would be premature to make any statement on matters such as those referred to in the latter part of the question.

TUESDAY, MARCH 2ND.

Rabies in London.

Mr. Walter Long, replying to a question put by Mr. Stephens, said that fresh cases of rabies had occurred recently within the metropolitan area, and the circumstances of the situation pointed clearly to the necessity for the issue of a muzzling order applicable to the whole of the metropolitan district irrespective of the boundaries of particular local authorities. The form which such an order should take was now engaging his attention, especially with regard to the description of muzzle to be used, and he hoped to be able to make an announcement shortly.

During the week marked copies of the following newspapers have been received:—*Glossop Times, Huntly Express, Derbyshire Times, Brighton Gazette, Richmond Herald, Surrey Comet, Hereford Times, Chatham News, Worcester Herald, Kidderminster Shuttle, Salisbury Journal, Herne Bay Argus, Times of India, Pioneer Mail, Worcestershire Advertiser, Newcastle Journal, Cheltenham Mercury, Kentish Express, Liverpool Daily Post, Hastings News, Scotsman, Western Morning News, Rocket, Bedfordshire Mercury, Architect, Rochester Journal, Oban Times, Birmingham Mail, Eastern Morning News, Yorkshire Post, Somerset County Herald, Wolverhampton Chronicle, Builder, Leicester Post, Leeds Mercury, Forfar Herald, Salisbury Journal, Manchester Courier, Australian Register, Sussex Daily News, Leamington News, Bristol Mercury, Portsmouth Times, Oldham Standard, Oswestry Advertiser, Express and Star, Sheffield Telegraph, Richmond Herald, Bristol Times, Gillingham Record, Carlisle Express, Litchfield Mercury, Sanitary Record, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, Mining Journal, Reading Mercury, Educational Times, City Press, Cape Times, Hertfordshire Mercury, Carlisle Patriot, Local Government Journal, Surrey Advertiser, West Middlesex Herald, East Anglian Daily Times, Devon and Exeter Gazette, Pioneer, Public Health, Stroud Journal, &c., &c.*

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second volume of 1896 was given in the issue of Dec. 26th last. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

"THE HIPPOCRATIC REVIVAL."

Indian.—The translation referred to in the Annotation under the above heading is that of Dr. Robert Fuchs, whose work is thus entitled: "Hippokrates' sämmtliche Werke ins Deutsch übertragen und ausführlich commentirt von Dr. Rob. Fuchs." (The collective works of Hippocrates translated into German and fully annotated by Dr. R. Fuchs.) It will consist of three volumes octavo, two of which are already published—Vol. I. costing 11 fr. 80 centimes, and Vol. II. 13 fr. 40 centimes. The translation improves upon (though it does not supersede) its predecessor—viz, that of Littré in French, and that of Dr. Francis Adams in English, the former (with revised text), published by Baillière, the latter (without text) by the old Sydenham Society. Even Dr. Fuchs's version will, in turn, have to be revised on the completion of the new recension of the Greek text by Kuhlewein, of which the first volume appeared rather more than a twelvemonth ago in the Bibliotheca Scriptorum Græcorum et Latinorum (Teubner, Leipzig).

M.D.—It is better to choose the school before purchasing particular text-books. All the principal London hospitals provide the necessary facilities for study. Our correspondent is advised to consult our most recent Students' Number (Sept. 5th, 1896), where he will find the scale of fees at the various hospitals and notes upon the most valuable text-books. The best course will be to settle upon the particular school first and then consult the Dean of the School concerning the date at which it will be advisable to enter and the classes that should be attended. Different lecturers prefer different text-books.

"DR. RENTOUL'S EXPENSES FUND."—THIRD LIST.

To the Editors of THE LANCET.

SIRS,—The following list contains all sums to hand up to date. Very little more than half the sum required has been subscribed. If the remaining 6500 or so of Dr. Rentoul's voters will send in a small subscription—even one shilling each—our object will be more than attained. I am, Sirs, yours faithfully,

Gateshead, Feb. 23rd, 1897. ALFRED COX, M.B. Durh., Hon. Sec.

THE NEW MORALITY.

UPON Feb. 23rd Mr. Millson, the medical officer of health for ton, made an application for the immediate burial of a ch had died from measles. The child had died on the 5th, and lying in the mortuary since the 12th. The parents were to bury the body, and the relieving officer refused to bury th without an order, because the parents were unmarried a Guardians considered that to bury the child at the expense parish would be to encourage people to live in a state of concub The next Burials Bill might well contain a clause to prevent idiotic conduct in future.

Hillary-street.—We do not think any useful purpose would be se by publishing the letter. It might provoke correspondence o acrimonious sort.

Locum T.—The clinical practice of a hospital is generally open to old students of that hospital. The London Post-Graduate Col might be of service to our correspondent, who should apply prospectus, &c., to Dr. Fletcher Little, 32, Harley-street, Cavendi square, W.

JAMES BARRY, M.D., THE FEMALE MEMBER OF THE ARM MEDICAL STAFF.

To the Editors of THE LANCET.

SIRS,—A few months ago some letters appeared in THE LANCE commenting upon the career of the late Dr. Barry, Inspector-Genera of Hospitals. I have just finished a charming book, "Fifty Years o my Life," by the Earl of Albemarle, and extract from p. 96, vol. ii., the following note which will no doubt interest some of your readers. Lord Albemarle was at the time returning from the Mauritius to England with his regiment, stopping while *en route* at the Cape, where he was a frequent guest of the then Governor-General, Lord Charles Somerset. He writes:—

> "There was at this time at the Cape a person whose eccentricities attracted universal attention—Dr. James Barry, staff surgeon to the garrison and the Governor's medical adviser. Lord Charles described him to me as the most skilful of physicians and the most wayward of men. He had lately been in professional attendance upon the Governor, who was somewhat fanciful about his health; but the Esculapius, taking umbrage at something said or done, had left his patient to prescribe for himself. I had heard so much of this capricious yet privileged gentleman that I had a great curiosity to see him. I shortly afterwards sat next him at dinner at one of the regimental messes. In this learned Pundit I beheld a beardless lad, apparently of my own age, with an unmistakeably Scotch type of countenance—reddish hair, high cheek-bones. There was a certain effeminacy in his manner which he seemed to be always striving to overcome. His style of conversation was greatly superior to that one usually heard at a mess-table in those days of non-competitive examination.
>
> "A mystery attached to Barry's whole professional career, which extended over more than half a century. While at the Cape he fought a duel, and was considered to be of a most quarrelsome disposition. He was frequently guilty of flagrant breaches of discipline, and on more than one occasion was sent home under arrest, but somehow or other his offences were always condoned at headquarters.
>
> "In Hart's Annual Army List for the year 1865 the name of James Barry, M.D., stands at the head of the list of Inspectors-General of Hospitals. In the July of that same year the *Times* one day announced the death of Dr. Barry, and the next day it was officially reported to the Horse Guards that the doctor was a woman. It is singular that neither the landlady of her lodging nor the black servant who had lived with her for years had the slightest suspicion of her sex. The late Mrs. Ward, daughter of Colonel Tidy, from whom I had these particulars, told me further that she believed the doctor to have been the legitimate granddaughter of a Scotch earl, whose name I do not now give, as I am unable to substantiate the correctness of my friend's surmise, and that the *soi-disant* James Barry adopted the medical profession from attachment to an army surgeon who has not been many years dead."

In later years when he visited Constantinople he met with another member of the same sex who had gone through some curious vicissitudes in the combatant line, Madame la Comtesse de Guilleminot, wife of his Excellency General Count de Guilleminot, Charles X.'s representative at the Porte. Of this lady he writes: "Nor was she, like her husband, any stranger to the battlefield. At the breaking out of the French Revolution she and her sister, les demoiselles Fering, entered Dumouriez' army as privates in a hussar regiment. They shared in most of the French victories at that period. Their gallantry in the field soon obtained for them commissions. The sister of Madame de Guilleminot was killed at the battle of Valmy (1792). One of the sisters—I forget which—received a sword of honour for her conduct in the face of the enemy. In the dignified and graceful deportment of the ambassadress of a Royal Court it was difficult to realise the idea of the young Republican *sabreuse*."—I am, Sirs, yours truly,

ALBERT A. GORE, Surgeon-Major-General.

Calcutta, Jan. 24th, 1897.

THE GENEROSITY OF JOHN ANDREWS, POTATO MERCHANT.

A CORRESPONDENT has sent us the following advertisement from a local paper:—

FREE Medical Attendance and Medicine.—Having succeeded in engaging the services of an eminent and very successful Professional Gentleman, I offer the above to all my customers.—John Andrews, Wholesale and Retail Provision and Potato Merchant, Lincoln-road, Fratton.

John Andrews's "eminent and very successful Professional Gentleman" is, of course, a quack, as no registered practitioner would lend his assistance to such a scheme for the inflation of the potato merchant's business. We ask John Andrews, therefore, how he will feel if his proprietary quack should kill some poor potato purchaser, either directly by administering the wrong remedy, or indirectly by preventing application to a properly informed practitioner. There is nothing in the business of a potato merchant calculated to steel the vendor's heart against human misery. Why, then, should John Andrews desire to inflict upon his customers the miseries that spring from quackery? But, to leave humanitarian questions aside and come to cold commercial reasoning, is John Andrews's departure likely to lead him to wealth? We think not. Personally we should prefer to get our potatoes where the price paid was made up to us in the sterling worth of the tubers. If we were offered more than potatoes for our money we should suspect that the potatoes were not worth the money asked for them, so that something had to be added. We should suspect, in this instance, that the wages of the quack had to come out of the price paid for the potatoes and should seek a market where the vendor's methods led to no suspicion of the excellence of his wares.

R. D. writes:—"Will any of the readers of THE LANCET kindly inform me how Sanguinal s prepared, its chemical composition and dose?"

M.D. asks if any readers of THE LANCET can refer him to literature on the subject of the progress of medicine during the present century?

Ignoramus.—The case is apparently one of molluscum fibrosum.

"ANTISEPTIC MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 27th, 1897, Dr. Playfair recommends a solution of "Creoline" as an efficient antiseptic for vaginal injections and ablution of the genitals. Before adopting "Creoline" one would like to know something more about its bactericidal and spore-killing properties. If a solution of 1 in 50 carbolic acid is not now recommended by Dr. Playfair as a reliable antiseptic, what strength of the "Creoline" solution would be necessary to fulfil the requirements?—I am, Sirs, yours truly,

Huyton, March 1st, 1897. R. L. WOOD.

To the Editors of THE LANCET.

SIRS,—I fear we have got into a maze over this perchloride of mercury as an antiseptic in midwifery. In THE LANCET of Feb. 20th we find Dr. Clement Godson writing: "Why the sublimate treatment should not be 'universally' adopted in private practice I am at a loss to understand," and in the very next issue of the same paper an equally eminent authority in the person of Dr. Playfair tells us "he should not recommend it as a thoroughly reliable antiseptic." I shall not place myself in the invidious position of the "fool stepping in where angels fear to tread," but will leave to those gentlemen the settlement of the question. I would, however, draw Dr. Playfair's attention to the fact that in quoting from his work of 1886 I gave the above date.

I am, Sirs, yours faithfully,

Ballincollig, March 2nd, 1897. JAMES J. HARDING.

X. Y. Z.—The medical man having been engaged must be paid. His services really begin with the arrangement entered into for attendance, and not with the first medical visit. But if before his medical services are required he should contract any illness, the nature of which would make it reasonably likely that he would not be well enough to fulfil his part of the engagement, the propriety of his resigning the case becomes obvious. The patient, however, should certainly make no arrangement with another medical man without communicating with the medical man engaged and ascertaining if he is able and willing to attend. The merits of the case rest on the special circumstances—the nature of the illness, for example.

PROOFS BEFORE LETTERS.

A MEDICAL man has in his possession two engravings after Gustave Doré's popular pictures "The Dream of Pilate's Wife" and "Moses and Aaron before Pharaoh." Both prints are proofs before letters, duly signed by the artist, and in perfect condition. The original cost was twenty-four guineas, and the owner will refuse no reasonable offer.

R. H.—It is difficult to lay down any general rule in this matter, but a completely malted or cooked food is probably more suitable since free undigested starch is not found in normal or natural infants' food.

A STRANGE CASE OF A FORGED MEDICAL CERTIFICATE.

A MAN, about thirty years of age, went to Llandaff, in Glamorganshire, on Jan. 20th and took lodgings, giving the name of "Jenkins." On Jan. 29th he removed to other lodgings, and on Feb. 8th he was found dead in bed. No papers were discovered in his possession except a certificate, which was as follows: "47, Bessborough-gardens, S.W., Jan. 2nd, 1897.—This is to certify that Mr. Jenkins is suffering from heart disease and may die at any moment.—R. N. Smith." On inquiries being made by the London police Mr. Nitch-Smith stated that the certificate was a forgery. It had apparently been written out or copied by the deceased himself, as it was in the same handwriting as the name "W. Jenkins" borne by the label on his portmanteau. His linen had been originally marked "W. Cross," but the name "W. Jenkins" had lately been written over these words. From this and some other facts the coroner, Mr. Bernard Reece, came to the conclusion that the name of the deceased was probably Cross, and he advised the jury to state in their verdict "that he was an unknown male person, that he was found dead in bed, and that he had died from rupture of the aorta." It was subsequently discovered that the deceased's name was Cross and that he came from York. The post-mortem examination showed that the medical certificate contained a correct diagnosis, but it has not been ascertained how the name of Mr. Nitch-Smith came to be attached to it, neither is it known why the deceased carried it about with him.

Dr. Tucker Wise thanks the numerous correspondents who have been good enough to reply to his inquiry respecting a convalescent home for a lady and her daughter. The ladies are now suited.

Mr. Norman B. Elliot.—The secretaries of the various associations will send their prospectuses. Our correspondent probably refers to a report made by THE LANCET on the relation of the medical profession to many of these associations. This report is published at the office of THE LANCET, price 1*s.*

FALSE COLOURS.

To the Editors of THE LANCET.

SIRS,—My attention has been called to your perfectly unexceptionable reply to a correspondent in THE LANCET of Feb. 27th. You say "the name of H. S. Schultess-Young, M.D., does not appear in the Medical Register." Of course it does not, nor on the roll of the Jockey Club, nor in that of aldermen who have passed the chair. But inasmuch as it might be hastily inferred that I have ever represented myself as an M.D. *tout court* or by any inference upon the Medical Register, allow me to contradict that supposition with great emphasis. Nor do I know of any person who has even by inference so described me. I have the misfortune to differ greatly from the orthodox medical man. Up to a certain point I have gladly undertaken and passed the admirable examinations imposed by the Conjoint Board, but beyond this the principles which I hold with the minority will not allow me to go. At the same time, I respect the opinion of the recognised medical professional world and do not seek to run counter to it. I claim no connexion with the British medical fraternity, but it is with regret. And the fact being as I have stated, you will, I hope, allow me the advantage of so assuring your professional readers, many of whom I am proud to claim as friends.

I am, Sirs, yours truly,

H. S. SCHULTESS-YOUNG, M.A., Balliol College, Oxon., Barrister-at-Law.

Essex-court, Temple, E.C., March 2nd, 1897.

*** We received from a correspondent a printed notice announcing a meeting of the National Anti-vaccination League. This notice gave a list of gentlemen who would support the chairman on the occasion. The last name in that list was "H. S. Schultess-Young, Esq., M.A., M.D.," and we were asked if the description was accurate. Our answer intimated that we believed the National Anti-Vaccination League to have misrepresented Mr. Schultess-Young's professional position and to have introduced that gentleman to the public under false colours, and we are glad to see that it was a correct answer. Mr. Schultess-Young is not a member of the Jockey Club, he tells us. Would he consider it fair of an Anti-Gambling League to announce him as a supporter *and* a member of the Jockey Club?—ED. L.

Phenad writes:—"Can any reader kindly tell me where, in Charcot's works, can be found his writings on Traumatic Neurosis and the Wasting of Muscles connected with that condition?"

M.R.C.S., L.S.A.—If the other medical man declined to meet our correspondent, it seems to us that our correspondent was at liberty to attend the case on his sole responsibility. The affair seems a very small one to cause anything like friction between two gentlemen of the same profession, and it is quite possible that the patient has caused the trouble by not understanding all the amenities.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The Milroy Lectures

ON

QUARANTINE.

Delivered at the Royal College of Physicians of London,

BY WILLIAM COLLINGRIDGE, M.A., LL.M., M.D., D.P.H. CANTAB.,

MEDICAL OFFICER OF HEALTH OF THE PORT OF LONDON.

LECTURE I.[1]

Delivered on March 11th.

MR. PRESIDENT AND GENTLEMEN,—I have, in the first place, to express my gratitude for my nomination to the honourable position of Milroy lecturer. I have selected as a subject Quarantine, limiting myself almost entirely to the progress of this system in England, its development, and subsequent supersession by the more rational system of medical inspection—a supersession which has only become possible on account of the great attention which in recent times has been paid to the sanitation of the country generally and to the gradual but steady growth of public opinion, which has been taught to rely upon the general health conditions of the whole country as the only means of preserving the people from the ravages of epidemic disease. I was led to choose this subject, not only because I deem it to be of the utmost practical importance to a commercial country, but also of the close connexion of the subject with the name of Dr. Gavin Milroy, the founder of these lectures. To his labours to overthrow an obsolete and oppressive system and to further the interests of commerce without jeopardising the public health is due to a large extent the present free and unrestricted intercourse enjoyed with all parts of the world by our merchant navy. Though it was not his lot to see the full fruition of his work, his name will always be honourably associated with the public health defence of the nation, to the furthering and the development of which he freely devoted so large a portion of his life work. The laws of quarantine, whatever form they may take, are framed with the idea of protecting a nation from the importation of disease, a risk which is practically in proportion to the extent of its trade. Such regulations are sanctioned in principle by international law, which, recognising the necessity for the constant interchange of goods and commodities between various States, allows each country to protect itself in any way that it may deem fit or expedient. Thus, whatever restrictions any one State may adopt, these must be submitted to by all others as the only conditions under which trade with such a State is possible. It is true that from time to time representations have been made by our Government to induce the relaxation of some unusually harsh or stringent regulation, but this has only been as a question of grace or favour when there appeared to be some exceptional reason, and not as a matter of international right.

Few subjects can have the same vital interest for a country such as England (whose very existence depends upon her commercial intercourse with other countries) as quarantine. On the one hand is the extreme importance of free and untrammelled commerce, and on the other the no less essential point of safeguarding in every possible way the public health. England, enjoying as she does trade with every part of the known world, is from this very fact exposed at all times, though with varying intensity, to the danger of the importation of epidemic disease. The history of quarantine in this country is that of a long and fierce struggle between these two great interests, which for many generations have been deemed to be more or less in conflict, but which the advancement of science and the development of rational principles have eventually brought into harmony and accord. It can be shown that the antagonism of these interests is more apparent than real, and it has happily been demonstrated that the utmost freedom of the trade of the country can be best promoted by the very means adopted for the preservation of the public health. It has frequently been asserted that quarantine is essentially a modern institution and that only within the last four hundred years has the system been actually in force. Thus thirty-five years ago a writer on quarantine says: "Quarantine has no ancient origin. In vain do we consult any of the writers of ancient or even middle ages for any traces of this system. In ancient times there were no bills of health or passports. The traveller passed from country to country unquestioned. There were at this time no officers of health or policemen. In the best days of Greece and Rome there were no lazarets, nor imprisonment of sick or healthy. The Mediterranean was indeed an open sea, and persons enjoyed free communication thereon. So recently as the fifteenth century was the first interruption to this state of affairs.'[2] This, however, is scarcely an accurate statement of the facts. In an elementary and crude form health precautions were taken long before this period, though obviously in the days when commerce (especially at sea) was in its infancy such measures were but imperfect, and necessarily attracted but little attention. Further, it is clear that so long as epidemics were deemed to be direct visitations of the Almighty as a punishment for some national offence, and the influence of communication by human agency was not recognised, it was not to be expected that any complete system should be in vogue for attempting to arrest the spread of disease. In connexion with quarantine it is not possible to overlook the directions given by the ancient lawgiver Moses, by which the Israelites became possessed of a code of sanitary law which, when divested of the ritual with which it was clothed, remains to this day as inculcating an example of a standard of sanitation which has scarcely been excelled by any nation, and certainly not yet reached by many who boast themselves of their civilisation. While there has been much discussion as to the nature of the disease referred to as leprosy in Leviticus xiii. and xiv., the position of the priest was clear. Acting with direct Divine authority, his duty was to examine each suspected case and decide as to whether the patient was suffering from the true disease or not. If the diagnosis was certain, then the sick man was declared unclean and was compulsorily isolated: "he is unclean, he shall dwell alone, without the camp shall his habitation be." If there was any doubt as to the nature of the disease, the patient was isolated for a period of seven days, at the end of which time he was again examined, and the period of seclusion was again and again repeated until the priest was able to definitely pronounce him clean or unclean. Again, in verses 47 to 59 instructions are given as to the purification of infected clothing; while in chapter xiv., verses 33 to 48, are laid down detailed regulations as to the cleansing, &c., of infected houses and clothing.

Except from the fact that under the Levitical law the priest acted with Divine authority, he fulfilled exactly the same duties and functions as the medical officer of health and sanitary inspector of our own days, and it is universally conceded that to the complete sanitary code under which they lived is due to a great extent the marvellous power of resistance to disease that has at all times characterised this remarkable nation.

In considering the question of quarantine it is important to exactly define the term, inasmuch as the word has been applied indiscriminately to many different systems of dealing with the prevention and control of infection. Thus it has even been applied to the period during which isolation is considered necessary after recovery from an infectious disease such as small-pox or scarlet fever. Limiting the word to measures designed to prevent the importation of disease into a country by means of maritime commerce, it may be defined as "the enforced detention and segregation of vessels arriving in a port, together with all persons and things on board, believed to be infected with the poison of certain epidemic diseases, for specified periods." At first such periods were purely arbitrary and bore no reference to the possible incubation period of the diseases against which they were directed.

The question of infection was but imperfectly realised, and beyond the general vague idea that a person coming from an infected place might in some way or other convey the pestilence, there were no definite opinions or theories on which to base any uniformity of practice as regards the period of segregation. Later, with the advancement of medical science,

[1] Lectures II. and III. will be delivered on March 16th and 18th respectively.

there was some attempt in a crude way to make the detention correspond with the supposed duration of incubation or latency of the poison. The essential point of quarantine, from its earliest inception up to its fully developed existence at the present day, is that it estimates the danger, and thereupon the precautions to be taken according to the state of health of the port whence the vessel has arrived, and has no reference to the condition as regards health or sickness of the vessel and its inhabitants. Though quarantine has been employed as a protection against many diseases, originally it was against the danger of plague only that it was directed. The whole theory of the system obviously rests on a belief in contagion. As soon as this was even suspected the natural sequence was to isolate those coming from suspected places as a means of protecting the general public. Dr. Granville, writing in 1819, states that the idea of segregation as a means of preservation can be traced to a much earlier epoch than the Crusades, for it is found explicitly mentioned in the Acts and Edicts of the Eastern Emperors during the sixth century. These, issued to prevent the importation of plague, ordained that those persons who came from an infected country should repair to a particular spot and remain there under observation for forty days, in order to ascertain whether they carried with them the seeds of the disorder. The first known law for the seclusion of persons from infected districts for a probationary period was enacted under the Emperor Justinian in 542. The earliest definite regulations against the spread of disease are those contained in letters sent by Duke Bernados to the prefects in 1374, when plague was devastating Lombardy, in which it was ordered that any person who should be attacked with any disease should forthwith leave the city or camp in which he was at the time and go into the fields or the woods until he either died or was set free, and further, following exactly the idea of the Jewish Levites, the priests of the parish churches were ordered under severe penalties to examine the sick and report the nature of their sickness to certain officers appointed for the purpose. Those who attended on the sick were ordered to remain isolated for at least ten days after the death of a patient before they held any communication with other persons. None but those appointed for the duty were to be allowed to attend upon the sick under penalty of confiscation of goods and life. In 1383, when the plague again invaded Lombardy, Bernados ordered that no person should be allowed to enter his kingdom from any infected place under the penalty of the yoke (*Sub pœna furcarum*); while in 1399 John Galeaz, Duke of Milan, for the same reason had guards placed at the gates of the city with instructions to prevent anyone entering who had come from a plague-stricken district. It was at the same time enacted that no house in which a case of plague had occurred should be again inhabited until it had been purified by fire and freely opened up for eight or ten days. These, however, were but solitary instances of precautionary measures. While trade was small and confined within certain narrow limits the danger from infection, scarcely yet believed in, called for no extraordinary measure of defence. Soon commenced the great movement of the Crusades. Originally inspired with the idea of preserving the Holy Land from the attacks of its enemies and of avenging the insults offered to Christianity, this movement rapidly grew and as rapidly degenerated, until the first great motive was almost entirely lost sight of in the unbounded opportunities it afforded for adventure, licence, and cupidity. In the first Crusade it was computed that nearly one million persons followed the standard of the Cross in its triumphant advance from Nice to Antioch, Edessa, and Jerusalem. But whatever the motive of those following the Crusades, and however sordid the reasons which guided them, one great result was the inevitable opening up of trade with the East. At the time the new disease—the plague—was attracting much attention, and it was naturally noticed that where plague was prevalent those who had kept aloof from the victims were by this fact to a certain extent protected therefrom. This isolation was at the best but partial, but its influence was observed, and its efficacy seen to be in proportion to its strictness. This gradually led to the idea that by preventing intercourse with infected places the importation of the pest might be entirely avoided. "Thus something in the shape of quarantine establishments began to be formed, not only to prevent intercourse with plague spots, but also to prevent free intercourse for some time after it was said to have subsided."[3] By continued experience of these facts, added to from time to time, developed the laws of quarantine, at first very imperfect and very varied in their form and restriction in various States, but all alike having their origin and bases in the one fundamental idea—viz., the doctrine of communication of disease by means of contagion. According to Boccaccio[4] Florence had adopted measures for its preservation from imported disease in 1384. To the Venetians, however, must be given credit for the first complete code of quarantine regulations. As early as the year 1150 they were said to have obtained from the Pope special sanction to enter into trade with the infidels of Alexandria and Aleppo and, according to Belou, had their own consul at the latter port before the middle of the fifteenth century. They were undoubtedly then and for a long time the only traders with Turkey. Venice was at that time the great centre of trade with the East, and its inhabitants were, therefore, more exposed to the importation of disease than those of any other State. According to Baker[5] it is probable that their first regulations were issued as early as 1127, but in 1448 a complete code was issued which served as a model for all others up to a very recent period. This code laid down as a principle that plague (against the introduction of which the law was established) "was a contagious disease capable of engendering a contagious matter, capable of adhering to certain inanimate substances, of being retained by them for an almost indefinite time without losing its activity, and, on the other hand, incapable of attracting itself to other inanimate substances and which might consequently be handled with absolute impunity and security. All merchants and persons coming from the Levant were compelled to remain in the house of St. Lazarus for a period of forty days before admission into the city. Thence is derived the term lazaret in use at the present day. There has always been some considerable doubt as to the origin of the period of forty days which gave rise to the name of the system. It seems probable that it was derived from the Jewish ceremonial, and was continued under various systems and laws until it became a settled period, the origin of which was lost, and the only justification for which was its antiquity. It ofttimes happens that a custom arising from some vague theory or speculation (which resting upon no sound basis is soon lost sight of) becomes after a lapse of time unassailable on account of its antiquity, and comes to be eventually considered as the result of the experience of ages, and as such venerated and preserved." The merchants settled in Turkey appeared to have formulated certain definite precautions against the plague, and our own merchants, who were not established in that country until close on the sixteenth century, doubtless influenced by their predecessors, at once began to adopt similar protective measures. These, however, were optional on their part and were not required by the law of the land. Bills of health were instituted by the Turkish Company for their own ships, for an English traveller at Aleppo mentions his having "a clean bill" (Moryson's Travels), and the English merchants at Aleppo established the same system as early as 1600.

In England in 1603 an Act for the relief and ordering of persons affected with plague was certainly passed, but this provided only for the isolation of persons in the country, and contained no provisions as to maritime quarantine. In the year 1636 the question was referred to the College of Physicians and certain "Directions" were issued by them. The second article stated: "It is likewise necessary that there be care taken that neither man nor goods may come from any suspected places without a certificate of health or else either to be sent suddenly away or to be put to the pest-house (or such like place) for forty days *according to the custom of Italy*." When these articles were re-published in 1665 the title of the second was changed from "Men and Goods from Infected Places" to "Prevention of Propagating the Infection from Place to Place," and reads: "As to the provisions already made by authority upon occasions of prohibiting persons and goods coming from infected places." From this may be inferred that quarantine having been at that time definitely established, it was no longer necessary to recommend its imposition.

The first commercial treaty between the Ottoman Empire and any European Power was that concluded in 1535 by Francis I. and Solyman the Magnificent. Venice followed

in 1580, and England a little later. In 1664, owing to the action of the Crown in destroying the monopoly of the Levant Company and throwing the trade open to all, the regulations became more stringent. These regulations required: (1) That no vessel should leave any port of Turkey or Egypt without a bill of health; (2) that all enumerated goods brought from Constantinople to Smyrna for Great Britain should, if there were any sickness at Constantinople, be landed and aired for twenty-one days; (3) that no goods from Cairo should be shipped at Alexandria when there was sickness there unless landed and aired for twenty-one days; (4) that no bill of health should be given until the expiration of forty days from even a single case of plague; and (5) that if the contagious sickness should appear on board any vessel in a Turkish or Egyptian port she should not be allowed to leave unless her cargo was landed and aired for at least forty days. It is especially noticeable that even at this early period the Levant Company took the precaution of inquiring into the health of the vessel at the port of departure. No provisions, however, were made for dealing with infected persons or for the disinfection of the vessel. As Sir James Parker says in his "Observations": "When we are certain as to the health of the crew of a ship we may make ourselves easy with regard to any fears which may arise from the merchandise" (p. 44), and that "the length of the voyage is a security against the importation of disease by persons" (p. 444). Before the Quarantine Act of 1754 a vessel from Turkey with a clean bill of health could land her passengers at any port, each one having his own individual patent. Dr. Pringle, in "Rational Inquiry," says: "Turkey being seldom free from plague, our trade there being increased so considerably within the last fifty years, it would be impossible for us to escape it (who have never made use of the Italian custom) if goods were sufficient to communicate it."

The first quarantine Act in England was passed in the ninth year of the reign of Queen Anne. Up to this period all quarantine regulations were issued by the King in Council without the intervention of Parliament. This is clearly shown in the preamble of the Act. This Act, like nearly all the subsequent ones, was passed under the influence of panic, the plague then raging in the Baltic. The Bill received Royal Assent eight days after it had been introduced into the Lower House, and came into force two days later. As an instance of the result of such hasty legislation it is to be noted that the power to open and air cargo (in which so much confidence was placed) was accidentally omitted, and only added by a special rider the day before the Royal Assent. Upon another alarm of plague at Marseilles in 1720 a second quarantine Act was passed in the same hasty manner; ordered to be drawn in December, it was read for the first time on Jan. 18th, and received Royal Assent on the 25th of the same month. The title was—"An Act for Repealing an Act and for the better preventing of plague being brought from foreign parts into Great Britain or Ireland, the isles of Guernsey, &c., and to hinder the spreading of infection." This Act was to continue in force for three years only. The outbreak of plague at Marseilles was the occasion for the passing of two Acts in the following session—the one "to enable His Majesty effectually to prohibit commerce for the space of twelve months with any country that is or shall be infected with plague," and the other "to prevent the clandestine running of goods and the danger of infection thereby and to prevent ships breaking their quarantine." The first received Royal Assent in February, 1721, and the second in March of the same year. All these three Acts of George I., being temporary, expired, whereupon the Act of Queen Anne again came into force. In the first year of the reign of George II. another Act, nearly word for word with that of George I., was passed. The power of prohibiting intercourse with any country for twelve months was again inserted, and also the power of preventing anyone coming from an infected place under a penalty of £500. The importer of prohibited goods was to forfeit double their value in addition to loss of ships and goods. Among the chief clauses of former Acts repealed was one empowering His Majesty in Council to make orders for the regulation of quarantine and another giving the power when plague existed in any foreign country to order vessels coming from infected places, or laden with goods from such places, or having on board any infected persons, to be burnt together with the whole or any part of the cargo. The order for opening and airing *after the quarantining of ships and crew* was continued. This Act, again, was only temporary and expired in 1731. In consequence, however, of the appearance of plague abroad it was revived in 1733 for a further period of two years. On its expiry in 1735 and until 1753 the Act of Queen Anne was once more the quarantine Act of the land. During the outbreak of plague in 1743 in the absence of the King the Lords of the Regency ordered all vessels from the Mediterranean to perform quarantine in Stangate Creek. In 1752 Parliament once more dealt seriously with the question, and two quarantine Acts were passed in the following year and came into force twelve months later. This was the first time that the Legislature had approached the subject deliberately and without the fear of an epidemic hanging over them, and as a consequence the Acts passed were far more thorough and complete. In the 26th Chapter George II. the 12th clause enacted: "That no goods nor merchandise liable to retain the infection of the plague and coming from the Levant without a clean bill of health shall be landed in Great Britain until it shall appear to the satisfaction of His Majesty that the same goods or merchandise have been sufficiently opened and aired at the lazarets of Malta, Ancona, Venice, Messina, Leghorn, Genoa, Marseilles, or one of them." The principal new provisions were as follows:—1. All vessels with plague being to the northward of Cape Finisterre were to proceed to New Grimsby (afterwards changed to St. Helens). 2. The master of a vessel performing quarantine was to deliver to the appointed officers a bill of health, consular manifest, log book, and journal under a penalty of £50. 3. The powers as to dealing with individuals were still very vaguely expressed: "They shall be subject to such orders as they receive from proper officers." 4. The omission of the words, "All ships coming from infected places or from any place known to trade with any place actually infected," and the substitution therefor of the words, "All ships, persons, and goods coming from places whence His Majesty in Council may deem it possible that infection may be brought." 5. The order for airing goods after quarantining of ships and crew was no longer specified. Up to this period all detention in quarantine had been carried out on board ship, but in 1752, the House having decided "that the present system of quarantine by airing goods on hoys and vessels is not well calculated to prevent infection, and is inconvenient and expensive to the merchant," further agreed, "that for the better and more effectual performance of quarantine a lazaret should be erected," and after considerable discussion Chedney-hill was selected as a suitable spot. Nothing, however, was done at the time, and twelve years passed without action, when, doubts having risen as to the sufficiency of the powers granted, a short Act was passed confirming the previous proceedings and voting the sum of £5000 to proceed with the work. This was the first step towards the provision of a lazaret in England, which, curiously enough, was never carried to completion, for after large sums had been expended on the scheme it was eventually discovered that the position was unsuitable. It was therefore abandoned and the materials sold. In spite, however, of the care bestowed upon the quarantine Act it was still from an administrative point of view very unsatisfactory. In all cases the details were left to the Privy Council, a body which had neither the time nor the means to attend to them properly. As an instance of this in 1770—i.e., twenty-seven years after passing the Act—an Order was issued that vessels from Dantzig or Pomerania were, when coming to the Thames or Medway, to perform quarantine for forty days in Stangate Creek, but if proceeding to any other port the officers of Customs were to appoint proper quarantine ground, from which it is clear that the Council had not already made such arrangements. This was, however, still more evident in 1790, when, on account of the prevalence of plague in Russia, seven stations were named in an Order of Council then issued. Again, in July, 1783, plague being prevalent in Poland, vessels coming thence were ordered to perform quarantine for forty days. The Privy Council had not considered the possibility of some of these vessels being laden with grain, which is not mentioned in the quarantine Act; and within a few days Edinburgh, being threatened with famine, presented a memorial showing the oversight and the serious consequences that might arise therefrom. A second Order was, therefore, hastily issued to permit all vessels laden solely with grain to discharge without any quarantine or airing of their cargoes, providing that the master made an oath that the crew were free from infection

Hosted by Google

and that the vessel had not communicated with any vessel from an infected place. In 1805 another Act was passed which, while in no way interfering with the existing system of quarantine, materially modified the charges which had been so serious a burden to the commerce of the country. A report of the Select Committee on the foreign trade of the country in 1824 gives some startling figures as to the burdensome character of these charges. It states that the quarantine charges in the case of a vessel with a clean bill of health amounted to 7*s.* 6*d.* per ton, and with a foul bill of health to no less than 15*s.* per ton register, 1*s.* extra being paid in London. Further, that these charges were levied upon the gross tonnage of the vessel, whether she carried a full cargo or not. The report goes on to say that, apart from the serious delay, in many cases the quarantine charges amounted to 35 per cent. of the value of the cargo, and one instance is given in which they exceeded 90 per cent., although there had been no sickness on board the vessel. The last quarantine Act of this country was the 6th George IV., cap. 78, which repealed all former regulations, and enacted that all vessels arriving from any places whence His Majesty by the advice of his Privy Council shall have declared it probable that the plague or other infectious disease or distemper highly dangerous to the health of His Majesty's subjects may be brought, and all persons and goods, shall be liable to quarantine. That all vessels from the continent of America or the West Indies (when yellow fever prevails there) shall come to anchor at certain appointed places in the port for the purpose of having the health of the crew ascertained. The opening and airing of such goods as were considered susceptible were still insisted on. By the 39 and 40 Vict., cap. 36, the powers of the Privy Council were ordered to be carried out by Her Majesty's Commissioners of Customs, and this continued until the repeal of the Quarantine Act by the Public Health Act, 1896. Long before this, however, the enormously increased importance of our foreign trade and the obvious futility of the strict enforcement of quarantine had excited the attention of thinking men. Dr. McLean was one of the principal movers in this direction, and his able statement of opinion led the House of Commons in 1817 to refer the matter to a Select Committee. This committee examined twenty medical witnesses, the majority of whom, however, were stated to have had no experience of the disease, and their report stated that all these gentlemen, with the exception of two, were in favour of the received opinion that the plague is communicable by contact only, and differs in this respect from epidemic fever. In this opinion the committee acquiesced, and added that they saw no reason to question the validity of the principles upon which such (quarantine) regulations appeared to have been adopted. This report is the more unsatisfactory inasmuch as the College of Physicians, when consulted by the Government in the previous year, had given their opinion in a much more guarded form as follows: "That although some epidemic diseases are not propagated by contagion, it is by no means proved that the plague is not contagious or that the regulations of plague police are useless or pernicious." "The doctrine of contagion appears to us to be wholly unshaken by any argument which Dr. McLean has adduced; at the same time we think it probable that some of the personal restrictions enforced in quarantine establishments might be modified without injury to the public health." Clearly showing that they recognised the unnecessary restrictions of the system as then carried out. Within a few years Sir Wm. Pym (the superintendent of quarantine) recommended considerable relaxation of quarantine, giving as his reason that he had never known a single instance of a case of plague occurring in a vessel from the Levant, and his belief that, with due regard to ventilation, infection would not spread. The only reasonable way of judging as to the actual value of the system was clearly to collect the experience of other European countries as well as our own. Progress in this direction was slow, for twenty years had elapsed before Sir Wm. Pym could say: "That there was no evidence to show that a single case of plague had ever been known to occur in any country from the manipulation of suspected or infected merchandise landed in lazarets." The records of lazarets also proved that the disease seldom or never spread from even the sick to any other of the inmates or to any of the officials of the establishment. As has been previously mentioned, up to the beginning of the present century quarantine had been directed against plague only. Yellow fever was at that time scarcely thought of, and cholera was not recognised as a danger to Europe. The experience of 1831-32 of quarantine as a protection against cholera was most unfavourable, and so clearly was this recognised that on the second visitation, in 1847, it was not relied upon. Nor was it at all evident that this country suffered in consequence or was more seriously affected than other European nations, which still kept up their rigorous system in spite of its obvious failure to protect them in their previous unsuccessful attempts to exclude the disease. A proposal for a general congress of delegates from States having ports on the Mediterranean had been made by the French Government in 1838, but fell through owing to various difficulties which arose. In the same year a proposal was made to send competent medical men to visit the chief European ports and collect information on the subject. Instead of this, however, Sir William Pym suggested that certain questions should be submitted to the consuls of Constantinople, Smyrna, Aleppo, Alexandria, Cairo, Odessa, and Malta asking for replies thereto. These questions were as follows: 1. Is plague communicated by contagion? 2. Is it communicated by contagion alone or by other means; if so, by what means? 3. Is actual contact with an infectious person necessary for communicating plague, or will a close approach to such a person communicate the disease? 4. Can substances which have been in contact with an infected person communicate the plague, and if so, what substances? 5. How long will the contagious matter of plague remain dormant in an infected person before it declares itself by evident symptoms? 6. How long will the contagious matter of plague when lodged in inanimate substances retain its infecting power? 7. What are the means by which substances containing contagious matter of plague can be purified?

A despatch of Lord Palmerston in 1839 to the English Ambassador in Constantinople on certain harsh measures enacted in Turkey is worthy of quotation as showing that the medical knowledge of the Government of the day was far in advance of its actual practice. "With reference to the proposed regulations, I have to instruct your Excellency to endeavour to strongly impress upon the Turkish Government that they would more effectually prevent the spreading of the plague by introducing cleanliness and ventilation into the city and suburbs of Constantinople than by such violent disturbance as is proposed with the domestic arrangement of families. It is quite certain that the plague is much aggravated, if not actually generated, by the want of cleanliness in streets, by the want of sufficient ventilation in houses, and by the want of proper drainage in places contiguous to habitations; and if the Turkish Government would in the first place apply vigorous measures to correct these evils they would strike at once to the causes of the disease, whereas the measures which they have now in contemplation will only be productive of inconvenience and suffering to numerous individuals."

A further attempt by the British Government to bring about a general conference in 1843 failed owing to the view of Austria that such conferences would be premature until exact information had been obtained from a committee of medical authorities appointed by each State to report as to (1) the maximum and minimum terms of quarantine for persons, (2) terms of quarantine necessary for goods and merchandise, and (3) the best measures for disinfection of objects susceptible of contagion.

Towards the close of 1844 a Commission was appointed by the Royal Academy of Medicine of France to report upon the whole subject. After a deliberation of more than twelve months they presented a most exhaustive report. Their general conclusions were that plague had arisen spontaneously in Egypt, Syria, Turkey, and in other countries, but could always be reasonably attributed to certain determinate conditions, the chief of which are residence upon marshy soil in low, crowded, badly ventilated dwellings, especially in a warm, moist climate and atmosphere, exposed to the actions of putrescent animal and vegetable matter, unwholesome and insufficient food, and great physical and moral wretchedness.[6] The characteristic features of epidemic diseases are:—1. They generally manifest in their progress three distinct periods of commencement, persistence, and decline, often displaying neither the

[6] M. Hamont states that Egypt before it came under Ottoman rule was a rich and prosperous country, and calculates that at one time its population must have been nearly one hundred millions, while in 1846 it was estimated at one and a half millions only. At the same time its social and physical condition has deteriorated at the same rate.

Hosted by Google

same symptoms, lesions, nor gravity during these periods. 2. During the prevalence of an epidemic other diseases are less prevalent, and they receive the stamp of the epidemic. 3. During an epidemic even persons in good health feel its morbific effects more or less. 4. Epidemics not unfrequently return and cease at the same season, and have usually the same duration. 5. An epidemic is often preceded by some other affection as a precursor. The Commission was of opinion that plague was not to any extent transmissible beyond or away from epidemic foci, for the following reasons. When an epidemic is dying out all, or nearly all, the sick recover and no new cases recur. There are still cases in hospital, all the conditions favourable to spread exist, and yet none takes place, and even an infected person coming from an epidemic focus is then to be feared no more than a sporadic case. If it is doubtful whether goods or clothing can convey plague during an epidemic, it is certain that they cannot after it has died away. They decided that the period of incubation was, as a general rule, from three to five days, and finally advised:—1. That for vessels having a medical officer on board from Egypt, Syria, or Turkey, with a clean bill of health the period of quarantine should be a full ten days calculating from the date of departure, provided that no case had occurred on board. That with a foul bill this period should be fifteen days for a healthy vessel. 2. For merchant vessels without a medical man the same period should be imposed, but that it should in all cases date from the time of arrival. The report itself is exceedingly valuable and instructive, but its conclusions do not in any way justify the severity of the practical recommendations.

In October 1844, Sir Wm. Pym, having visited all the principal Mediterranean ports, was of opinion that the periods of quarantine both for persons and vessels might be considerably reduced and in some cases altogether abolished, especially in the case of vessels from the Black Sea and those which had crossed the Atlantic. During the Crimean War an interesting experiment was made as to the value of quarantine as a safeguard against cholera. Owing to the exigencies of international warfare the whole system of quarantine throughout the Mediterranean and Baltic was practically suspended. Although cholera existed on the Continent, it was seen that many places freely exposed to risk of infection from the arrival of infected vessels and the landing of sick persons suffered less than on former occasions. This was notably the case with Malta and Gibraltar.

In 1865 was published the eighth report of the Medical Officer of the Privy Council. The remarks therein made by Sir (then Mr.) John Simon, marking by their clearness, power, and scientific accuracy a distinct epoch in the position of this country, remain and will remain as a record of his acumen and farsightedness in this as in many other directions. He says: "The precautions generally which may be taken against contagious disease are of two kinds—first, if possible, to prevent the entrance of the contagion; secondly, if the contagion be present, to annihilate as far as possible the circumstances which favour its spread. Thus, as regards cholera, a first, an incalculably important, question to be answered by those who have to care for the public health of a country is the question whether by any measures of quarantine they can provide that all contagion of the disease shall be kept outside the limits of the land. Subject to one qualification, which is not an important one for the present argument, it may, I think, be accepted as certain that quarantine conducted with extreme rigour and with the precision of a chemical experiment will keep cholera out of every part of Europe in which the extremely difficult conditions can be absolutely fulfilled; and thus, if I speak to the dry question of medical practice, I have no hesitation in saying that England ought to resist cholera by quarantine. On the other hand, though I cannot pretend to discuss with any kind of authority the non-medical aspects of the question, it would be mere pedantry for me to ignore that facts which are of common notoriety and considerations which are of common sense conflict with that medical conclusion. A quarantine which is ineffective is a mere irrational derangement of commerce, and a quarantine of the kind which ensures success is more easily imagined than realised. Only in proportion as a community lives apart from the great highways and emporia of commerce or is ready and able to treat its commerce as a subordinate political interest—only in such proportion can quarantine be made effectual for protecting it. In proportion as these circumstances are reversed it becomes impossible to reduce to practice the paper plausibilities of quarantine. The conditions which have to be fulfilled are conditions of national seclusion, and fulfilment of such conditions by England would involve fundamental changes in the most established habits of the country. In order to illustrate this view the medical postulates of quarantine, purporting to be effectual, cannot rest satisfied with excluding from entry such persons as are obviously sick, but, indispensably for its purpose, must always refuse to admit the healthy till they shall have passed in perfectly non-infectious circumstances at least as many days of isolation as the disease can have days of incubation or latency; this condition often involving as its consequence that if one case of disease arise among a number of persons in quarantine the whole number of apparently healthy must re-commence their period of probation, and this perhaps again and again. Now, setting aside as not essential to quarantine the cruelties which its mal-administration involves, and which in practice are almost identical with its exercise; criticising only the conditions which quarantine, if it is to be effective, must involve; and for the moment not even counting as an objection the cost of that gigantic establishment which has to be permanently maintained in order to meet occasional exigencies, I here insist only upon the restrictions. Considering what they, when carried into effect, must involve—what inconvenience to persons, what interruptions to commerce, and on how vast a scale and for what indefinite duration—no one can expect, in regard of great trading communities, that Governments, if they go so far as to enact, will have much success in enforcing quarantine. Against the efficiency of it when enacted there operate some of the strongest law-breaking influences—on the one hand instincts of contempt for the narrow self-protectiveness which it represents, and on the other those eager commercial instincts which now mainly govern the world. Contraband of quarantine, like ordinary smuggling, is developed as soon as the inducements for it are considerable. And thus, practically speaking, where great commercial countries are concerned it can scarcely be dreamt that quarantine restrictions will be anything better than elaborate illustrations of leakiness. In respect of England, moreover, there are other facts to be stated. In 1832–33, when some sort of quarantine against cholera was adopted here, the results gave no encouragement to repetition. Then followed the erroneous belief (which subsequent better knowledge has corrected) that the spread of cholera is unaffected by human intercourse. Under these and other influences the thought of quarantine in England became more and more obsolete, and the possibility of enforcing it, if ever so much desired, fell more and more towards nothingness. Probably there was the practical conviction that against any contagious disease on the continent of Europe quarantine of the utmost strictness which England could hope to attain would not give results worth the sacrifice. I dare say that quarantine in England was never otherwise than very lax, and at all events it has for many years past in every medical sense been abolished. Further, with its virtual extinction the establishment for giving it effect has declined. As successive Governments advanced further and further in relinquishing what probably at its best was only a sham of quarantine corresponding reductions of establishments were made. And the result of the entire progress may be told in these very few words—that at the present moment England has not in readiness the means of properly quarantining a single vessel. It is not for me to say that this state of things may be deemed final. But if reversal of that policy which it expresses were ever so much desired it could not be effected offhand. Enormous first expenditure of money in creation of proper lazarets would be wanted as well as subsequent very large annual outlays for maintaining the necessary establishments. And the time which would be required for bringing the organism into work forbids the supposition that this could ever be done on emergency. So far in England, under present circumstances, quarantine against cholera, as existing in the countries which are nearest to us is a precaution of which there can be no serious thought. Were the country ever so ready to endure those extreme restrictions, without which the whole thing is fruitless and absurd, the means for imposing them do not exist. To extemporise a cordon sanitaire is simply and totally impossible, and no partial quarantine can be relied upon for national purposes. Not only as regards cholera, but generally as regards all contagious diseases, the position

Hosted by Google

which now has to be recognised and dealt with is that contagion current on the continent of Europe must be deemed virtually current in England."[7]

This clearly represented the position of the country at that time with reference to quarantine as a means of defence, and from this position there has since been no reason to recede. But quarantine was not yet got rid of. Originally established to prevent the importation of disease, when this object was shown to be futile the system was still retained in order to prevent interruption to trade. It was clear that while other countries kept up the practice any official abandonment would only lead to an indiscriminate quarantining of British vessels. That this was no imaginary danger has been shown on many occasions. In 1853 the countries where quarantine was most rigorously carried out were Spain, Portugal, Greece, and Sweden. As soon as cholera appeared in this country Spain called upon Gibraltar to impose quarantine upon all arrivals from our ports, and on account of some delay all communication with the mainland was at once cut off except such as was carried on by smugglers, and in self-defence the authorities were compelled to yield. This same pressure during the present year has caused Gibraltar to impose quarantine upon vessels from Indian ports. Any hesitation to comply would have invited a complete cessation of the important defence works in course of construction there. Again, in 1825, when some vessels with foul bills of health were admitted to pratique by order of the Government, the whole United Kingdom was put in quarantine by the Mediterranean Powers and every arrival from Great Britain subjected to a lengthy detention. And, to quote one more recent instance, the *Helene*, a small German vessel, which arrived in London in August, 1893, with two cases of cholera on board, was refused pratique at a South American port nine months later, the reason assigned being that she had not yet undergone quarantine, having been only subjected to disinfection in this country.

At the close of the cholera epidemic in 1851, on the invitation of the French Government, delegates once more attended at Paris from France, Great Britain, Austria, Russia, Turkey, Greece, Spain, Portugal, and some other Powers to consider the question. They decided that henceforth only two degrees of quarantine should be recognised—viz, quarantine of observation and quarantine of rigour, the quarantine of suspicion being abolished. That only two forms of bills of health should be allowed—viz., clean and foul, and that these should be granted after the health of the port of departure had been thoroughly ascertained and not on conjecture, as heretofore. That the measures taken should apply equally to the vessel, crew, and passengers in consequence of the health of the port of departure, and that no regard should be paid to the condition of the health or sickness during the voyage in determining the nature of the quarantine which was to be directed against the infected country generally. The diseases against which quarantine was to be employed were reduced to three—viz., cholera, yellow fever, and plague. It is worthy of note that Austria opposed the inclusion of cholera on the ground that she had tested quarantine against it in 1831 and found it not only useless but dangerous. England, France, and Sardinia alone opposed quarantine entirely and stated that they had retained it only in consequence of the position of other European Powers. Spain and Portugal, while admitting that the utmost protection could be afforded by measures of general sanitation, held that till these have been universally carried out reliance must be placed upon compulsory segregation. The final decision, carried only by five votes, was that all arrivals from a cholera-infected port should be liable to five days' full quarantine, the voyage being included, but that if any case had occurred on the voyage the detention should date from the time of the arrival. That it was not necessary to land cargoes, but that free ventilation on board was sufficient. Power, however, was to be given to any State to impose a shorter quarantine than three days on vessels coming from a port which, though still healthy, was in close proximity to or in communication with one already declared infected. For yellow fever the minimum detention was fixed at from five to seven days, and the maximum at from seven to fifteen days. If the voyage exceeded thirty days, if there were no sickness on board during the voyage, and if the vessel was in good sanitary condition on arrival, this term might be reduced to three days. If the voyage were of more than ten days' duration and no sickness had occurred on board, simple aeration would suffice for the cargo. But if the voyage was shorter than ten days, or if there had been any case on board, then the cargo might be required to be landed and disinfected. As against plague the minimum detention was fixed at ten days, and the maximum at fifteen, and this could only be performed at such ports as were duly provided with lazarets and appliances for landing and disinfecting persons and cargo. Disinfection was to be required for all highly and moderately susceptible goods. Further to increase the value of the bills of health it was decided that a clean bill should not be granted until the expiry of a specified period after the certified cessation of disease in a port. This period was fixed at ten days for cholera, thirty days for yellow fever, and thirty for plague. Although quarantine proper was to be limited to these three diseases, still a local authority was to be allowed to impose a mitigated quarantine in the case of a vessel on board of which typhus fever or small-pox actually existed at the time of arrival.

To mark the Conference's view of the importance of the sanitary condition of vessels it was decided that foul or filthy ships should be treated as though they carried foul bills. Unfortunately, however, no corresponding privileges were given to those vessels which arrived in good sanitary condition. A Convention drawn upon the lines of the decision of the Conference was agreed to by France, Sardinia, Portugal, Tuscany, and Turkey. England naturally declined to accept these terms on account of the severe and unnecessary restrictions. It is a somewhat significant fact that in more than one of the countries agreeing to this convention regulations became thereafter more rigorous than before.

Thus, although the deliberations of the Conference lasted for more than three months, the total result was unsatisfactory in the extreme. It had begun to be understood in this country that whatever advantages were supposed to be gained by quarantine could be more effectually obtained by other and more reasonable methods. In 1848, when the old system was discontinued upon the recommendation of Dr. Southwood Smith, it was explained that in the place of the rigorous detention of vessels from infected ports with their crews and passengers for a lengthy period a system of strict sanitary supervision of the vessels themselves and of all persons on board by a medical officer should be substituted. The Social Science Quarantine Committee in 1861, after having submitted a long list of questions to Her Majesty's Customs and others, from the information thus obtained formulated a most valuable report which was published by the Board of Trade. After stating that the object was to amend and utilise, not to destroy, the existing machinery, they reported that while the practice of quarantine varied in different ports there were great difficulties in obtaining information on account of the lack of systematic and accurate reports on the subject; that bills of health were drawn up in different forms and from various sources of information, often erroneous and affording no real guarantee as to the health of the country; that even in strict quarantine countries the regulations were of necessity relaxed at certain times—notably in case of war or the arrival of particular vessels; that lazarets and other arrangements were not adapted for their purpose, causing not only discomfort but even actual injury to persons detained in them; that the division of cargoes into classes of susceptible and non-susceptible, &c., was utterly valueless, and that, moreover, the spread of disease from a cargo was practically unknown; that those countries which were most rigorous in the enforcement of quarantine were no more exempt from epidemic diseases than those which adopted more lenient and simple precautions; that stringency was apt to defeat its object by leading to concealment; and that the sanitary arrangements of ships and ports were, generally speaking, exceedingly faulty. They therefore recommended: — 1. That under ordinary circumstances vessels which have had no sickness during the voyage and are in good sanitary condition on arrival should be admitted to free pratique without regard to the health of the port of departure. 2. When any detention of a vessel is necessary, either from the fact of sickness existing or on account of the foul or unwholesome condition of the vessel, a careful examination should be made of her and of all the persons on board by the quarantine medical officer, who should have the power to adopt, and should be charged with the responsibility of adopting, such measures as each case demands. The

[7] Report of the Medical Officer of the Privy Council, p. 40.

healthy should not be detained, and the sick should be removed to hospital as speedily as possible. Where small-pox exists on board a ship all unprotected persons should be vaccinated. 3. Vessels from abroad should be required to pump out their bilge water and clean their bilges before entering harbour, and the hold should be aired so far as possible before arrival. 4. Before a bill of health is given an examination should be made as to the sanitary condition of the vessel and the health of the crew, and the results of such examination noted on such document. 5. Medical quarantine officers should be required to keep accurate records of all matters relating to quarantine, and to prepare an annual report thereon.

The Erasmus Wilson Lectures

ON

THE PATHOLOGY OF THE LYMPHADENOID STRUCTURES.[1]

Delivered at the Royal College of Surgeons of England on March 1st, 3rd, and 5th, 1897,

BY W. G. SPENCER, M.S., M.B. LOND., F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS AND THROAT DEPARTMENT, WESTMINSTER HOSPITAL, AND LECTURER ON PHYSIOLOGY AT WESTMINSTER HOSPITAL MEDICAL SCHOOL.

LECTURE II.[2]

Delivered on March 3rd.

THE THYMUS.

GENTLEMEN,—The thymus is a remarkable organ, since it appears under three different forms. The primary thymus is composed of glandular epithelial cells, the secondary of lymphadenoid tissue, and the tertiary of fat. The primary thymus of glandular epithelium persists in some fish and secretes mucus; in the higher animals all that normally remains of it at birth are the concentric cell masses of Hassall. But Chiari[3] has shown that the cysts of the thymus which are found in infants, and to which the names of tubercle, syphilis, and abscesses have often been given according as their contents are caseous, solid, or puriform, are really true degeneration cysts lined by epithelium. These cysts represent the mucus secreting follicles of fish, which usually shrivel up into the concentric bodies, but may be found in the kitten as cysts lined by ciliated epithelium (Capobianco, *vide infra*). Epithelial remnants may also be the source of dermoid cysts, of malignant tumours—in Rolleston's[4] case as mucus secreting cells, or as epithelioma with true nest cells in the case described by Paviot and Gerest.[5] It is this primary thymus which is so closely related in its manner of origin to the thyroid gland. The secondary thymus, composed of lymphadenoid tissue, is a paired organ in birds. In mammals it is generally fused into one mass, which may have processes running up to the trachea representing the position of the primary diverticula. It has a peculiar arrangement of lobes and lobules, which distinguishes it from compound lymphatic glands. Each lobule is divided into a polyhedral cortex, having a germinating mass of cells and a medulla in which are found the concentric bodies. It is an organ which is richly supplied with blood, and the lymphatics leading off from the sinuses round the polyhedral follicles, after passing through the glands of the superior mediastinum, join the thoracic and right lymphatic duct to enter the veins of the neck. This lymphadenoid thymus, which commences to develop and remove the primary one about the fourth month, reaches its fullest development at birth. It certainly forms leucocytes, and during embryonic life at least red cells also, even in the highest mammals. The formation of leucocytes takes place earlier in the thymus than in the lymphatic glands. The thymus was first removed by Friedleben,[6] and his experiments have lately been repeated by Tarulli.[7] The young animals did not suffer from the loss. After birth it persists for a variable length of time up till puberty before it changes into the tertiary fat organs. It persists throughout life as a lymph-adenoid organ in some fish and reptiles, and may be met with in man long after puberty. The thymus may be diseased at birth owing to the cysts already mentioned. If hæmorrhage into these cysts or inflammation sets in rapidly increasing dyspnœa may ensue (Durante[8]), and the organ being hidden behind the sternum the cause of the dyspnœa may remain unsuspected. Sudden death from asphyxia frequently occurs from this cause in newborn infants and young children, and the enlarged thymus is only discovered post mortem. A large lymphadenoid thymus may be met with in adults associated with enlarged thyroid, and may form an additional unsuspected cause of dyspnœa which is not relieved by an operation upon the thyroid. Perhaps the pressure on the large veins at the root of the neck causes venous congestion and enlargement of the thymus, as happens in the spleen from similar causes. The thymus is also enlarged in the cases of lymphadenoma to be afterwards referred to. The tertiary fat thymus is always to be found in man, the peculiar lobulation of the fat showing that it has been derived by a metamorphosis of the lymphadenoid organ (Waldeyer,[9] Capobianco[10]). The fat is, however, but a quiescent stage of lymphadenoid tissue as is the yellow marrow of bone, and so reappearance of the lymphadenoid tissue takes place in adults suffering from lymphadenoma. A large lymphadenoid thymus is met with in diseases accompanied by anæmia, such as Addison's disease and the acromegaly of Marie, &c. There is some antagonism between the thyroid and thymus gland. The thymus is well developed in cretins; feeding with the thymus gland relieves exophthalmic goitre.[11] Siegel cured a child aged two and a half years threatened with asphyxia by displacing the enlarged thymus from the anterior mediastinum into the subcutaneous tissue.[12]

LYMPHATIC GLANDS.

True lymphatic glands are only found in birds and mammals. The thymus supplies their place in the lower forms. There are also lymphadenoid masses in connexion with the kidney of fish; the salamander has lymphadenoid tissue round its liver. In the frog the thymus early changes into fat, and the spleen has no Malpighian bodies, but there are besides the marrow, which is red in the spring, also rudimentary tonsils and the fat bodies in the abdomen, which are during part of the year lymphoid in structure. Lymphatic glands are few and small in rodents, more numerous in the carnivora and ungulates, but most numerous in man (Gulland[13]). In some mammals, such as the sheep, small glands, intermediate between the spleen and lymph glands, are found in front of the vertebræ in the mesentery and contain blood in them, the so-called hæmolymph gland.[14] But they have not been shown to exist in man. Lymphatic glands are developed relatively late in embryonic life, they do not appear until after the middle of this period—i.e., after the thymus has become developed as a lymph-adenoid organ. Lymphatic glands vary much, some having only a single follicle forming a minute mass from 1 to 2 mm. in diameter. There are others with more than one follicle varying in number up to the ordinary compound lymphatic gland. Lymphatic glands undergo retrograde metamorphosis, especially in old age, and turn into fat like the bone marrow and thymus. But at any time they may be excited to regeneration, a compound gland may develop from a single follicle, or a new formation of

lymphatic glands take place in connective tissue. The process is the same as in the embryonic formation, leucocytes emigrate into the connective tissue and split up its fibres into retiform tissue. The only difference in the lymphadenoid tissue arising from the excitation of diseased products is that the arrangement of germ centres is not so well defined as in the normal gland.

Lymphatic glands have two functions, the production of leucocytes and the protection of the circulation from the entrance of organisms through the skin and mucous membranes. Organisms may be carried to a gland where they are arrested and ultimately destroyed, or they may grow through the gland, destroying it meanwhile, and so reach the circulation. But those of the highest virulence either enter by the bloodvessels and so escape the lymph glands or they pass at once through the gland without stopping and without setting up any reaction. Besides the lymphatic glands, through which all lymph has to pass, the mucous membranes of the respiratory and alimentary canal have a further means of preventing the entrance of organisms and their products in the shape of follicles situated in it, and there is also a considerable development of the tissue in the mucous and sub-mucous coats not specially gathered up into follicles, but diffused throughout it. This development of lymphadenoid tissue becomes more striking when we see how slight is the development of lymphadenoid tissue in connexion with the pelvis of the kidney, the ureters, and the bladder, and the absence of lymphadenoid tissue in connexion with the cerebro-spinal lymph spaces. The cerebro-spinal fluid is practically lymph in an extensive system of sinuses, yet this lymph passes directly into the venous blood, and there are therefore cell products or metabolites due to brain activity which do not need to be rendered harmless before they are allowed to enter the circulation. A diffuse form of lymphadenoid tissue is met with in the mucosa and sub-mucosa of the conjunctivæ, nose, pharynx, larynx, bronchi, stomach, and intestines, in some parts less marked than in others—e.g., in the œsophagus; but in all parts capable of being abnormally developed in the course of disease. Of the special masses of lymphadenoid tissue the palatal tonsils develop around epithelial sacs which remain as the crypts. The pharyngeal tonsil forms around the epithelial crypt developed in connexion with the hypophysis, and the lingual tonsil is a lymphadenoid mass about the foramen cæcum. The solitary and agminated follicles develop in the mucosa between the glandular epithelium of the ileum, cæcum, and appendix. But the function of this tissue is not limited to arresting or rendering harmless materials about to be absorbed, the follicles also produce cells which freely pass into the mouth, intestine, and bronchi, and prevent the excessive development of organisms in these canals. Foreign bodies can easily enter through an intact mucous membrane, whereas in the case of the skin there must be a lesion of the surface or the material must be well rubbed into the mouths of the hair follicles and sweat glands. Coal dust when inhaled passes through the intact epithelium of the bronchi and alveoli to the neighbouring glands. Carmine which has been mixed with the food of the animal passes out through the intact wall of the intestines, especially by way of the solitary and agminated follicles. Of all micro-organisms the tubercle bacillus has yielded most interesting experimental results. If a culture of tubercle bacilli be injected into the trachea of an animal the bacilli pass through the intact mucous membrane and infect the neighbouring glands. Similar results may be obtained by feeding animals on material containing tubercle or anthrax bacilli, which pass through the uninjured intestine. In the human subject in connexion with tuberculous glands in the neck a visible lesion in the mouth or on the tonsil is quite the exception, a carious tooth being the only frequent one. Indeed, the local inflammation causing hypertrophy of the tonsil or adenoid vegetations seems very rarely to be followed by tuberculous glands in the neck. It is quite the exception to see a combination of hypertrophied tonsils or adenoid vegetation and tuberculous glands in the same patient.

Lymphatic glands and follicles may be affected through the circulation, like the spleen and bone marrow. The affections are generally sub-acute or chronic rather than acute. The specific fevers, syphilis, and tubercle when generalised, may cause a widespread enlargement. The acutest form of general enlargement is the hæmorrhagic swelling characteristic of plague. More frequently diseases are due to direct infection of the follicles and infection of the glands by way of the lymphatics. In acute inflammation there is an increased circulation through the gland with a more rapid production of cells. The inflammation may subside owing either to the destruction of the organisms or because the infection has passed on through the gland into the circulation. One of or all the follicles of the gland may pass from the stage of inflammation to that of suppuration, which may extend outside the gland, the lymphadenoid tissue forming a slough in the centre. This is often seen in gonorrhœal buboes and in the intestinal follicles. Another form of acute inflammation is due to streptococci, as in diphtheria, scarlet fever, and erysipelatous complications; there is then marked infiltration of the gland and the surrounding connective tissue with œdema and fibrin. A chronic inflammation of lymph glands and follicles consists at first of a simple overgrowth of the gland formed chiefly by an increased number of cells in the meshes, and the distinction between the germ follicles and the medulla is less clearly marked. But if the chronic inflammation continues there is an increase in the connective tissue derived from the capsule and septa of the gland, and thus the amount of lymphadenoid tissue, including cells, becomes really diminished although the gland may be apparently enlarged. The stopping power of lymphatic gland tissue varies with the different diseases. Thus, in syphilis, although the gland enlarges there is no evidence of any power of arresting disease. The attempt to arrest syphilis by excising the hard sore and the glands has been a complete failure. On the other hand, it seems to have a considerable power in preventing the extension of tubercle. Usually the tubercle bacilli are caught in the germ follicle, where they form tubercles which afterwards caseate. Less often there is no definite formation of tubercle, or indeed of giant cells, nor is there any early tendency to caseate, but diffuse infiltration of the whole gland structure. It is then extremely difficult to distinguish a gland so affected by tubercle from lymphadenomatous glands by simple microscopic examination, although inoculation if successful may demonstrate that the disease was of a tuberculous nature. Repair and healing take place in lymph glands by scar tissue derived from the connective tissue, capsules, and septa, the lymphadenoid tissue proper taking no share in it.

LYMPHADENOMA.

Lymphadenoma is a suitable term for those affections the various forms of which have one feature in common—viz., a growth of lymphadenoid tissue closely resembling in structure that of lymphatic gland. The subdivisions of lymphadenoma are excessively confusing from the tendency to classify by some one prominent feature and from the desire of splitting up clinical cases into an endless number of groups. The names in use are employed in very different senses, and it would be difficult to find any two cases of a series which do not exhibit striking differences. We must anticipate in the classification of cases of lymphadenoma the recognition of its definite cause, and as there are many indications that the causes are not very far separated from that of syphilis and tubercle we can take as our guide the analogy of tubercle and distinguish a local disease, local lymphadenoma, from a general disease, generalised lymphadenoma or lymphadenomatosis, in which lymphadenoid tissue is involved in widely separated positions, although to a very various extent. Of local lymphadenoma we may further mark out two kinds, one simple or benign local lymphadenoma, in which the cause is apparently more or less continuously acting upon the lymphadenomatous tissue from the surface of the mucous membrane or skin; whereas in the more malignant form, malignant local lymphadenoma, there is a lack of evidence as to the external source of the irritation, or such irritation as may be present is inadequate, the essential feature being the continuous proliferation of cells from some cause which must be within the tumour itself. So also in generalised lymphadenoma or lymphadenomatosis we can recognise the local origin of the growth from some cause which widely affects lymphadenoid tissue, but in which the development of the disease can be controlled by treatment, and, on the other hand, a malignant generalised lymphadenoma in which the cause must reside within the growths themselves as in other forms of cancer. In a tabular form, then, the divisions of lymphadenoma are: (*a*) Local lymphadenoma: (1) simple or benign; and (2) malignant. (*b*) Generalised lymphadenoma or lymphadenomatosis: (1) benign; and (2) malignant. The other names in common use—leucocythæmia

Hosted by Google

or leukæmia, pseudo-leukæmia, Hodgkin's disease, and lymphosarcoma—I can affirm from an examination of the literature of the subject to be used scarcely by any two writers in the same sense. The term "Hodgkin's disease" should be employed as synonymous with "lymphadenoma"; Dr. Hodgkin's paper is entitled "Some Morbid Appearances of the Absorbent Glands and the Spleen." He did not describe any such a well-defined disease as, for instance, did Dr. Addison. The attempt to apply his name to any special form of lymphadenoma cannot be sustained. Leucocythæmia or leukæmia (some writers distinguish the two) are names for one of the signs of the disease which may be present or absent, or absent in the early stages, present later, and finally disappear before death. It has often been used as a name without there being evidence that the blood was even examined; its existence may have been overlooked where only one examination has been made, on account of the sudden variations. An increase of leucocytes may arise from some temporary inflammatory cause or be merely relative owing to the diminution of red cells. Some writers call a slight increase of white cells leucocytosis, some call it pseudo-leukæmia, and others use the term pseudo-leukæmia when no increase of white cells was noticed. Another complexity has been added since the division of the white corpuscles, for which we are indebted to Professor Ehrlich. From a careful comparison between the microscopical examination of the blood, the clinical features of the disease, and the results of the necropsy I do not believe that we can decide from the examination of the blood alone as to the parts of the lymphadenoid organs specially affected. For instance, cases have been called "myelogenous leucocythæmia" from one examination of the blood in the entire absence of clinical and post-mortem confirmation. Lymphosarcoma is a term liable to be confounded with sarcoma growing in a lymphatic gland. It is often used as indistinguishable from lymphadenoma; for instance, we read of multiple "lymphosarcoma" being cured by arsenic. Dr. Wilks[15] was really the first to bring this subject of lymphadenoma forward, and it was after his earlier observations had been made that he lighted on Hodgkin's paper, which had until then received no attention. His name "anæmia lymphatica" for the generalised form is better than "leucocythæmia," seeing that it is the decrease of red cells and not the increase of the white ones which is the more important. The only rational way at present of grouping the various cases of lymphadenoma is by taking the point of origin in each case. Although we remain as yet ignorant as to the causes, yet by considering the probable ways of entry we shall be prepared to receive further evidence of causation without having to make extensive changes in the system of classification. This will be much better than naming the case after some one particular sign of the disease which happens to be prominent.

[15] Wilks: Guy's Hospital Reports, 1856, p. 103; 1859, p. 109; and 1865 p. 56.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.—A deputation from this society was appointed to interview the Members of Parliament representing the counties of Lancashire and Cheshire for the purpose of obtaining their active opposition to Mr. Tatton Egerton's Bill for the Registration of Midwives. Along with the deputation from the Lancashire and Cheshire Branch of the British Medical Association they were, through the kindness of Mr. J. W. Maclure, received by a number of local members and others, among whom were Mr. J. W. Maclure (in the chair), Lord Balcarres, Sir Henry Howorth, Sir Blundell Maple, Mr. T. P. O'Connor, Mr. Tatton Egerton, Colonel Forster, Mr. Isaacson, Mr. Lees Knowles, and Mr. C. Schwann. Two members of the Lancashire and Cheshire branch having spoken, a member of the deputation addressed the meeting and stated several points which were essential to the drafting of any Bill aiming at the registration and control of midwives. The danger of all such legislation was touched on, and objection was taken to the Bill as a whole, on the ground that any amendment thereof would, in order to be satisfactory, entirely alter the complexion of it, and that it could not be expected or hoped that such radical alterations would even probably be effected during the progress of the Bill through committee. In an after discussion of an informal nature with some of the members the deputation had a further opportunity of explaining their views.

The Arris and Gale Lectures

ON

SOME POINTS IN THE PATHOLOGY OF HEART DISEASE.

Delivered at the Royal College of Surgeons of England on Feb. 22nd, 24th, and 26th, 1897,

BY ERNEST H. STARLING, M.D., M.R.C.P. LOND.,

JOINT LECTURER ON PHYSIOLOGY AT GUY'S HOSPITAL.

LECTURE III.[1]

ON THE CAUSATION OF DROPSY IN HEART DISEASE.

MR. PRESIDENT AND GENTLEMEN,—The main object of the experiments on the circulation which I described in the last lecture was to determine so far as possible the factors which are responsible for the production of the anasarca and serous effusions met with in heart disease. In dealing with this question it must be remembered that dropsy consists in the accumulation of lymph or the fluid which has transuded from the bloodvessels in the connective tissue spaces, and depends therefore on a disturbance of the balance which normally exists between the production and absorption of lymph in the affected parts. Since the questions to be considered and their experimental investigation differ according as we are considering the production of anasarca or of serous effusions, I shall treat of the causation of dropsy in these two situations under separate headings, although I hope to show that the factors involved in each case are essentially identical. We may deal first with the question of the production of œdema in the connective tissues in the limbs. In my previous lectures on the principles of lymph production I dealt chiefly with the lymph flow from the abdominal organs, since the existence of a continuous flow from the abdominal viscera in the animal at rest makes this region the most adapted for experimental investigation. As a result of my experiments I came to the conclusion that lymph formation must be looked upon as the product of two factors—viz., the pressure of the blood in the capillaries and the permeability of the capillary wall. The process, therefore, is analogous to filtration—increase of the filtration pressure or diminution of the resistance of the filtering membrane increasing the amount of filtrate—i.e., lymph. When we attempt to test the truth of these principles on the lymph production in the limbs, we are met at once by the difficulty that if one places a cannula in one of the large lymphatics in the limb of an animal at rest one obtains no lymph flow at all. In order to obtain any lymph in this manner it is necessary to knead or massage the limb or to carry out passive movements. We must not, however, conclude from the absence of a lymph flow through the lymphatics that there is no lymph produced in the resting limb, since it is quite possible that lymph or fluid may have transuded from one portion of the capillaries and been absorbed by another portion. We have, in fact, in order to explain the absence of lymph flow from the resting limb, to consider not only the mechanism of the lymph production, but also the absorption of the transuded fluid. In this case we can evidently leave the absorption by way of the lymphatics out of the question, since it is the flow, or rather the absence of flow, along these vessels that we are considering. It seems, indeed, probable that the lymphatic drainage system of the connective tissues carries on its functions only during activity of the limb or its component parts. All the experiments which have been made on the flow of lymph from the limb lymphatics bring out strongly the fact that extensive alterations in the filtration pressure—i.e., the pressure in the blood-capillaries—cause only slight changes in the lymph flow, in no way comparable to the effect which would be produced by similar changes in the vessels of the abdominal viscera. We must conclude, therefore, that, compared with the latter, the limb capillaries are extremely impermeable—i.e., present a great resistance to filtration. Now, as I have shown, the permeability of a

[1] Lectures I. and II. appeared in THE LANCET of Feb. 27th and March 6th respectively.

Hosted by Google

capillary wall, as of an organic filter, may affect not only the quantity of fluid transuding from the plasma under a given pressure, but also the composition of this fluid. Thus if we filter serum through filter paper the filtrate has exactly the same composition as the original fluid. If we use a Chamberland filter we find that the filtrate contains less proteid than the original fluid, and the proteid which passes through becomes less and less as the filtration is continued and the pores become more and more stopped by the retained proteid. By soaking the porous cell in a solution of gelatin so as to fill all its interstices with this substance we may, as Martin has shown, make this impermeability to proteids absolute, without in any way affecting the passage of water and salts through the filter. Hence we may use this method to obtain the crystalloids and water of the serum or blood absolutely free from the proteids and other colloid constituents of these fluids. We should therefore expect to find that the capillaries of the limbs, which present so great a resistance to filtration, would at the same time keep back the larger part of the proteids, so that the transuded fluid would be extremely poor in these substances. Now, on analysing the few drops of lymph which can be squeezed from a cannula placed in a lymphatic of the limb, we find that the difference between the composition of this lymph and that obtained from the permeable capillaries of the liver is by no means so great as we should expect from the relative effects of changes of intra-capillary pressure on the amounts of transudation in these two situations. Whereas the lymph derived from the liver contains from 6 to 8 per cent. of proteids (almost as much as the blood-plasma itself), that from a lymphatic of the limbs contains 2, 3, or 4 per cent. We have no right, however, to assume that the lymph as obtained from a cannula in a limb lymphatic represents in composition the lymph or interstitial fluid which is transuded from the capillaries. Indeed, it may be shown that the fluid flowing from the cannula must be considerably more concentrated than the original transudation. In order to understand this point we must consider carefully the conditions under which transudation and absorption are going on at all times in the connective tissues of the limb.

We have already seen that, given a certain degree of impermeability, the filtrate through a membrane contains less proteids than the original fluid. Now we know in the case of dissolved salts that the separation of water from the solution, leading to the concentration of such a solution, involves the expenditure of a considerable amount of energy. This concentration can be effected by evaporating the solution, in which case the necessary energy is supplied in the form of heat; but we may effect this concentration in a different way. A porous cell is permeable to water and dissolved salts; if, however, an amorphous precipitate of copper ferro-cyanide be deposited in the meshes or pores of such a filter it will then be found that the cell wall is no longer permeable to dissolved salts. A cell wall thus impregnated with copper ferro-cyanide is generally spoken of as a semi-permeable membrane. If such a cell be filled with a solution of salt or other crystalloid, and be then sealed and immersed in distilled water, it will be found that, although no salt can diffuse out of the cell, water diffuses into the cell until the pressure inside has attained a considerable magnitude. In the few cases in which it has been possible to measure the pressure thus produced it has been found that this "osmotic pressure" is approximately equal to that which the dissolved molecules would exert if they were present in the cell in the form of gas. If now the pressure inside the cell be raised artificially above the osmotic pressure of the dissolved substance, pure water will pass out of the cell, and the solution inside will become more concentrated, until its osmotic pressure is equal to the hydrostatic pressure in the cell. The question now arises whether similar reasoning may not hold good in the case of the separation of colloids—such as proteids—from their solutions. Since the osmotic pressure of a substance is equal to that pressure which it would possess were it in the form of a gas, it is evident that in a solution of given strength the osmotic pressure must be smaller the greater the molecular weight of the substance—i.e., the smaller the number of molecules present. Although our knowledge of the nature and properties of colloids is still very imperfect, it seems practically certain that all of them possess enormous molecules, if not in point of size, at any rate in point of molecular weight. That their size is probably also large seems to be indicated by the difficulty with which these colloids pass through fairly coarse pores, such as those of a Chamberland filter. We should, therefore, expect that the proteids of the plasma and serum, if colloids can be regarded as at all analogous to crystalloids in their solution, would possess a certain osmotic pressure, small, no doubt, in comparison with the huge osmotic pressures of fairly dilute salt solutions, but still large enough to be considered in relation to the forces acting in the body. In attempting to determine directly the osmotic pressures of salt solutions, the very size of the results is the cause of great difficulty in their accurate measurement, the vessels leaking or bursting before the final pressure has been reached. Moreover, it seems to be very difficult to prepare a reliable semi-permeable cell by Pfeffer's method. In the case of the colloids of serum these difficulties do not arise. We have only to soak any disc of parchment, peritoneal membrane, or even fine wire gauze in gelatin to obtain a membrane perfectly impermeable to colloids, and the pressures we have to deal with are so small that a very little support of the membrane suffices to prevent leakage. If, for instance, we take a thistle funnel, over the open end of which such a membrane is stretched, fill its bulb with serum, and immerse it mouth downwards in salt solution (isotonic or even hypertonic as compared with the serum), we find that fluid (water and salt) passes into the serum and causes a considerable elevation of fluid in the stem of the funnel, which may amount to a height corresponding to a pressure of from 30 to 40 mm. Hg. Since this result is invariably obtained and the height of the pressure is proportional to the amount of proteids contained in the serum, we must look upon from 30 to 40 mm. Hg. as representing the osmotic pressure of the proteids of the serum. If at the beginning of the experiment the stem be also filled with serum to a height of, say, a metre, the fluid rapidly sinks in the stem, owing to the filtration of water and salt through the gelatin membrane, until the height is equal to 30 or 40 mm. Hg. So that to concentrate a proteid solution by filtration one must employ a pressure which is greater than the osmotic pressure of the proteid in solution; and in this concentration, since the osmotic pressure of the fluid increases, its potential energy, as measured by it power of attracting water and raising it to a height, is increased. We must therefore conclude that whenever a proteid solution is filtered through a membrane more or less impermeable to proteids, with the production of a more watery filtrate, a certain amount of energy is used up in the process, the hydrostatic pressure used for the filtration being converted into an increased osmotic pressure of the concentrated fluid. In such a case the fluid within the cell or vessel will attract the more watery fluid outside with a force represented by the difference in the osmotic pressure of the two fluids, whereas the force causing filtration or transudation is only represented by the amount by which the hydrostatic pressure inside the vessel exceeds this difference in the osmotic pressure.

We may now apply these principles to the conditions as they exist in the living body. As the blood passes from the arterioles through the capillaries into the veins it gets from a region of high into a region of low pressure. We may therefore, in order to dissociate more easily the processes occurring in the tissues, divide the capillaries into two parts—the arterial and the venous capillaries. In the arterial capillaries the blood plasma is at a pressure which exceeds the osmotic pressure of the plasma proteids. From these capillaries, therefore, a transudation of a watery fluid takes place much poorer in proteids than the plasma. The transudation thus produced reaches and bathes the outside of the venous capillaries. In these vessels, however, the pressure of the blood has fallen to a point below that corresponding to the osmotic pressure of the plasma proteids. Here, therefore, the force tending to the absorption of the water and salts—viz., the osmotic pressure of the plasma—is greater than the force causing transudation—viz., the hydrostatic pressure of the blood in the vessels. Now this absorption will affect only water and salts, since we know of no mechanism by means of which the proteid lying outside the vessel wall could be absorbed. We have therefore a continual exudation of a fluid very poor in proteid from the arterial capillaries and a continual taking up of the water and salts of this fluid by the venous capillaries. It is evident that the resultant of these two processes, the fluid which remains in the tissue spaces and is squeezed along the lymphatics with every movement of the limb or pressure on the spaces, must contain a considerably higher percentage of proteids than was contained in the fluid as it originally left the bloodvessels. Hence the difference between

Hosted by Google

the proteid percentage of liver lymph and limb lymph is by no means so great as would correspond to the difference in the permeability of the vessels in these two situations. When the fact of the absorption of fluid by the bloodvessels was once definitely established it seemed difficult to account for the presence or use of the lymphatics. Why should a complete and special system of absorbents be developed in all parts of the body if the whole office of absorption might be and was normally carried out by the bloodvessels? If we assume, as many authorities do, that the vascular wall has the power of actively taking up proteids and fluids from the surrounding tissue spaces no work is left for the absorbents. There appear to be no grounds for such an assumption, and I have sought in vain for any evidence for the absorption of proteids by the bloodvessels. Any proteid which leaves these vessels with the transuded lymph is lost for the time to the vascular system. If it is not used up by the tissue elements it must be collected by the lymphatics and restored to the vascular system by way of the thoracic or right lymphatic duct. It is on account of this inability of the bloodvessels to absorb effusions which contain more than a certain percentage of proteids that it is so often necessary to remove such effusions by surgical means. In such cases there is no lack of bloodvessels in close connexion with the fluid to be absorbed. It is, however, the blocking of the surrounding tissue spaces and obliteration of the lymphatic channels which determines the failure of absorption. It might be thought that this impermeability of the limb capillaries would be of disadvantage to the organism, since it limits the supply of proteids to the tissues of the limb. So far as we know, however, the proteid metabolism of these tissues forms but a very small fraction of the total metabolism of the body. Increased functional activity of the muscles, for instance, causes hardly any increase in the excretion of urea, while a marked increase is observed in the excretion of CO_2—that is to say, the muscle derives its food supply chiefly from the diffusible constituents (e.g., dextrose) of the blood. On the other hand, it would be extremely disadvantageous if the limb capillaries at all approached the liver capillaries, or even those of the intestines, in permeability. The smallest change in position, in consequence of the effects of gravity, would alter the pressure in the capillaries and cause large changes in the amount of lymph poured out, so that the legs would have to be provided with a series of lymph hearts to pump up the lymph which was turned out in the upright position. We have an opportunity of observing the effects of such changes in the hydrostatic pressure of the blood in cases where the permeability of the capillaries has been altered in consequence of inflammatory conditions. In such cases the beneficial effects of raising the limb in relieving tension—i.e., the distension of the tissue spaces by lymph—are well known.

We may now proceed to utilise the knowledge we have gained of the factors regulating the formation and composition of lymph in the limbs under normal conditions for the purpose of explaining the œdema of heart disease. As I have already mentioned, it has been customary to classify the œdema of heart disease with that due to venous obstruction, such as occurs when the large veins are pressed upon by growths or obstructed by thrombi. The production of œdema in consequence of venous obstruction was shown to be possible by the experiments of Paschutin and Emminghaus, and still more strikingly by Ranvier's experiment. The latter observer showed that if the inferior vena cava were ligatured and the sciatic nerve on one side cut, the leg on the same side became œdematous in consequence of the increased transudation induced by the high pressure in the capillaries. Many authors have observed the production of œdema as the result of an elastic ligature round the upper part of a limb. In all these cases, however, the rise of pressure in the capillaries necessary to produce œdema is very considerable; and Cohnheim himself, in discussing the point, concludes that the œdema is not sufficiently explained by the increased venous pressure in heart disease. In my last lecture I showed that the immediate as well as the remote effect of heart failure, however caused, was to bring about a diminution rather than an increase of capillary pressure, and we know that such a diminution of pressure in the capillaries causes increased absorption from the connective tissue spaces, and therefore a less amount of fluid in these spaces. An experiment of Cohnheim gives some clue to the explanation of the difficulty. It is well known that ligature of one femoral vein in the dog is not followed by any œdema. Cohnheim found, however, that if a dog be bled every few days for a week or two before the operation, so as to render his blood hydræmic, ligature of one femoral vein gives rise to œdema of the leg, extending all round the neighbourhood of the wound. If the hydræmia be brought about just before the ligature, by bleeding the dog and injecting a corresponding amount of saline fluid, no œdema results. Cohnheim concludes, therefore, that long continued hydræmia alters and injures the vessel wall, so making it more permeable, so that a rise of capillary pressure, which would be without effect in a normal animal, is now able to considerably increase the lymph transudation and cause distension of the tissue spaces. We have seen that, although there is no plethora, there is hydræmia in heart disease. Moreover, the nutrition of the vessel wall is injuriously affected by the failure of the circulation and consequent absence of a proper renewal of oxygen and nutrient material to the capillary wall. These factors coöperate in increasing the permeability of the wall to such an extent that a very slight increase in the intra-capillary pressure, such as may be brought about by a dependent position of any part, is sufficient to cause increased transudation and consequent œdema. In heart disease the capillary pressure is not higher, but rather lower, than in a normal animal. The dropsy is entirely conditioned by the state of the capillary wall.

In adopting this view as to the exclusive responsibility of the change in the capillary wall for the œdema of heart disease we are confronted by an apparent difficulty. We are accustomed to regard increased permeability as connoting not only an increase in the amount of fluid transuded, but also in the concentration of the fluid. Now if we analyse the fluid of œdema in heart disease we find that it contains only from 0·3 to 0·5 per cent. of proteids—i.e., considerably less than that found in the lymph from the limbs of normal animals. How, then, can we speak of the permeability of the vessel wall being increased under these conditions? I think the answer lies in the fact that increased concentration is not the necessary sequence of increased permeability. Thus, to return to the example of various filters, a porous cell saturated with gelatin presents a much greater resistance to filtration than does a film of peritoneal membrane which has been soaked in the same substance. Yet in each case the composition of the filtrate is the same, no proteids having come through. On the other hand, we may increase the permeability of the gelatinised Chamberland filter by boiling it and dissolving out all the gelatin. After this, not only is the amount of the filtrate under a given pressure increased, but the filtrate is qualitatively different in that it now contains proteid. It is quite possible that the changes wrought on the capillary wall by the mingled effects of hydræmia and stagnation of the blood have the same result as the thinning of the colloid filtering membrane—i.e., merely a quickening of filtration. On the other hand, the changes met with in inflammation are much severer and have for an effect the utter alteration of the quality of the membrane.

It being allowed, then, that the qualitative permeability may be normal while the quantitative permeability is increased, it is easy to account for the small amount of proteid present in the œdema fluid. For then not only is the original blood plasma poorer in proteid than it is normally, but the chief factor tending to increase the concentration—i.e., the absorption by the bloodvessels—is practically abolished. For the effect of the slow blood current is to equalise the pressures in veins and arteries, so that if the hydrostatic pressure in the arteries is sufficient to cause abnormal transudation an almost equal amount of fluid will be poured out by the veins. Absorption by the bloodvessels can now only occur when the capillary pressure in a part is considerably reduced by raising it above the level of the heart. It seems probable that the obstruction to the flow of lymph from the thoracic duct into the blood, as well as the distension of the duct from the largely increased lymph flow from the liver, may contribute to the production of œdema in the rest of the body. This factor must, however, be only a subordinate one, and is far transcended in importance by the increased transudation from the vessels which occurs in this disease.

The production of effusions into the serous cavities.—The arrangement of the vascular supply is so different in the case of the pleural and peritoneal cavities that it is desirable to consider the causation of effusion into these two cavities separately, and we will deal first with the question of pleuritic effusion. On this point a number of experiments were made by Leathes and myself, and we found that the

Hosted by Google

conditions governing increased effusion into these cavities are very similar to those we have just studied in the limbs. Thus in the latter we saw that so long as the vessels are normal it is impossible by any moderate increase in the capillary pressure to produce any marked œdema or effusion. On the other hand, it is easy to produce effusion by alterations in the vessel wall, and when such alterations have been effected every rise of pressure is followed by a considerable increase in transudation. In our experiments on the pleura we attempted, first, to produce effusion by increasing the capillary pressure in the part. Since the blood from the pleural parietes has several different channels of exit, the only method one can use to bring about a rise of capillary pressure is the injection of large quantities of normal saline solution into the circulation. We tried at the same time to intensify the rise by obstructing the vena azygos at its opening into the superior vena cava, and also ligatured both thoracic ducts. Although in these experiments an enormous degree of œdema was found in the retro-peritoneal tissue and in the posterior mediastinum the pleural cavities themselves contained only 2 or 3 c.c. of fluid. On the other hand, the injection of small amounts of jequirity into the pleural cavity produced a typical pleuritis, with destruction of the endothelium, and fibrinous and serous exudations. In such cases the injection of large quantities of normal saline into the circulation caused a large and rapid transudation of fluid through the injured capillaries into the pleural cavities, and the death of the animal within two or three hours from asphyxia. A simple destruction of the pleural endothelium, as by scalding or the injection of sodium fluoride into the pleural cavities, had no effect in producing effusion. We therefore concluded that for the production of effusion it was necessary that the tissues, and especially the blood-vessels in the peripleural connective tissue, should be affected. Any fluid which is poured out in the tissues lying under the pleural endothelium, whether in the chest wall or in the mediastinal tissues, rapidly finds its way into the pleural cavities, so that it is possible to kill an animal by asphyxia by allowing fluid to run into the carotid sheath, which is continuous with the connective tissue spaces of the posterior mediastinum. In such cases at the death of the animal both pleural cavities are found full of fluid, although the endothelium separating the mediastinum from the pleural cavity is still intact, and presents no apparent openings for the passage of the fluid.

The hydrothorax, therefore, of heart disease must, like the œdema of the limbs, depend in the first place on an alteration and increased permeability of the vessel wall occasioned by the stagnation and poor quality of the blood. Since, moreover, we have seen that obstruction of the thoracic duct causes distension of the mediastinal tissues, and that fluid can pass easily from these tissues into the pleural cavities, it seems probable that the obstruction to the flow of lymph into the blood through the duct, which is present in uncompensated heart disease, must materially contribute to the hydrothorax. Whether an increased transudation in the lungs may also aid in the production of the effusion we have no experimental evidence to show.

In the peritoneal cavity there are two distinct systems of capillaries, either of which might be responsible for the production of ascites. On the one hand, we have the capillaries of the spleen and alimentary canal, which form the radicles of the portal vein; on the other, the liver capillaries which drain into the hepatic vein. We have already seen that these capillaries differ markedly both in their permeability and in the effect on the pressure in them of various changes in the circulation. Heart failure, for instance, such as is brought about by injection of oil into the pericardium causes a marked rise of pressure in the hepatic capillaries, but a fall of pressure in the intestinal capillaries. With regard to the ascites determined by changes in the portal system of capillaries, it would seem that the result of increased flow of lymph in this capillary region depends on the condition of the peritoneal endothelium. Thus ligature of the portal vein causes a very large increase of the lymph flow from the thoracic duct, but only a slight exudation of fluid into the peritoneal cavity; if, on the other hand, we increase the permeability of these capillaries by plunging several coils of intestine into hot water, or even into distilled water, at the temperature of the body, we find that, although the lymph flow from the thoracic duct is hardly changed, there is a considerable exudation into the peritoneal cavity. In the latter case the transudation from the intestinal capillaries, instead of being confined beneath the endothelium and compelled to traverse the lymphatics towards the cisterna and thoracic duct, can escape easily through the damaged endothelium and adopts this path of least resistance. In heart disease, however, the most important source of the ascitic fluid is probably the liver. Even in the normal animal a slight exaggeration of the conditions present in heart disease will induce an ascites, which seems to be derived from the liver capillaries. Thus in one experiment I ligatured the thoracic duct and obstructed the inferior vena cava above the liver in order to raise the capillary pressures in this organ. A condition of hydræmic plethora was then produced by the injection of 1500 c.c. of normal saline solution. Two hours later the animal was killed and the abdomen found to contain 100 c.c. of fluid. In another experiment the lymphatics of the liver were ligatured as they pass out of the portal fissure, and hydræmic plethora produced as before. In this case 230 c.c. of fluid were found in the peritoneum.

Since we know that the capillary pressure in the liver is largely increased in heart disease—and these experiments show that even in the normal animal an increased transudation in the liver combined with obstruction to the lymph flow causes ascites—we are warranted in concluding that the chief, if not the only, source of the ascitic fluid in this disease is the capillaries of the liver. This conclusion is confirmed to some extent by Halliburton's analyses of the ascitic fluid in different disorders. He found that in heart disease the concentration in proteids of this fluid was greater than when the ascites was due to portal obstruction or cirrhosis of the liver. We know now that a similar difference in concentration obtains between liver lymph and lymph from other parts of the body, and it is on this account that the effusion in heart disease is more concentrated than that found in other disorders. From these experiments one would expect that ascites should be one of the most constant and earliest symptoms of heart disease. I do not know how far clinical observations would bear out this conclusion.

In these lectures I have endeavoured to give a connected account of the factors which lead to the production of dropsy in consequence of the failure of the heart-pump. The views which I have put forward must, however, be regarded only as the most probable in the light of our present physiological and pathological knowledge, and it is quite possible that we may have to modify them to some extent on further investigation of the subject.

SANITARY INSPECTORS' ASSOCIATION.—The fourteenth annual dinner of the Sanitary Inspectors' Association was held at the Holborn Restaurant on March 6th, Sir John Hutton, the President, being in the chair. Among those present were the Archdeacon of London, Sir Arthur Arnold, Professor Corfield, Professor Crookshank, Mr. T. P. Teale, Dr. J. M. Rhodes, Dr. W. J. Collins, and Mr. Shirley Murphy. The chairman, in the course of the evening, said that the association was founded in 1883 and now had very nearly 700 members. Many branches had been established during last year. The association was at present giving much attention to the subjects of superannuation, fixity of tenure, and the holding of examinations which sanitary inspectors will be required to pass.

ROYAL SURREY COUNTY HOSPITAL.—The annual meeting of the Royal Surrey County Hospital at Guildford was held on Feb. 27th, the Rev. Dr. Haig-Brown presiding. The report for the year ending Dec. 31st, 1896, showed that the income for the year was £4970 and the expenditure £4280. A long discussion took place in reference to home visits which had for many years been paid to patients in Guildford by the house surgeon of the infirmary, but which had been discontinued since the end of 1896 in pursuance of an arrangement made by the governors in 1891. It seems that when the hospital was first opened it acquired the funds and took over the work of a previously existing dispensary whose members were entitled to be visited by the medical officer at their own homes in the event of their being unable to attend at the dispensary. The hospital authorities had not bound themselves to carry on home visits permanently, and in discontinuing them they were within their rights; but there now seemed to be a strong feeling in favour of the visits being resumed. In the result it was resolved to appoint a committee to confer with the municipal authorities on the subject and to consider all the aspects of the question.

The Lettsomian Lectures

ON

DISEASES OF THE NOSE AND THROAT IN RELATION TO GENERAL MEDICINE.

Delivered before the Medical Society of London,

BY F. DE HAVILLAND HALL, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE WESTMINSTER HOSPITAL, AND JOINT LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE IN THE WESTMINSTER HOSPITAL MEDICAL SCHOOL.

LECTURE III.[1]

Delivered on March 1st, 1897.

ANEURYSM.

MR. PRESIDENT AND GENTLEMEN, — In aneurysm of the aorta the laryngoscope is oftentimes of inestimable service in enabling the practitioner to make an early diagnosis, and consequently to allow of the institution of prompt treatment. It may be laid down as an axiom that when the left vocal cord is immobile in the cadaveric position pressure of an aneurysm upon the recurrent laryngeal nerve is the first thing to be thought of, and it is only after an aneurysm has been excluded that other causes for the paralysis of the laryngeal muscles need be considered. This is more especially the case in males between the ages of thirty and sixty years. It must be remembered that, in accordance with Semon's law, "there is proclivity of the abductor fibres of the recurrent nerve to become affected sooner than the adductor fibres, or even exclusively, in cases of undoubted central or peripheral injury, or disease of the roots or trunks of the pneumogastric, spinal accessory, or recurrent nerves," consequently the first effect of pressure on the recurrent nerve is to cause abductor paralysis on the affected side. Now, unilateral abductor paralysis presents such slight symptoms that in the absence of a laryngoscopic examination it is generally overlooked; still, numerous cases have been recorded in which this condition has been observed as a symptom of thoracic aneurysm. When, however, the adductor fibres become implicated and the cord passes into the cadaveric position the effect on the voice is so marked that the patient feels that something is amiss with him, and consequently seeks advice. In looking over the notes of sixteen private cases of aneurysm of which I have full particulars I find that they were all males, the youngest twenty-nine and the eldest sixty-one years of age, the average age being almost exactly forty-seven years. Of these sixteen cases, in one case there was bilateral paralysis of the abductors, the left vocal cord was in the cadaveric position in eight, in five there was impaired movement (loss of abduction) of the left vocal cord, and in two the laryngoscopic appearances were normal. The right vocal cord was only affected in the case of bilateral paralysis of the abductors. The proportion of cases in which the left vocal cord was partly or completely paralysed is, of course, much greater in my practice than in ordinary general practice, inasmuch as several of the patients consulted me on account of hoarseness and had no suspicion that they were suffering from any serious affection; still, this only emphasises the importance of a laryngoscopic examination in all cases of hoarseness, and, as I have said before, a loss of mobility of the left vocal cord in a middle-aged male, especially if the cord is in the cadaveric position, should at once arouse the suspicion of an intra-thoracic aneurysm. The reason why the right vocal cord is so seldom affected depends upon anatomical considerations; the right recurrent nerve winds round the subclavian artery, and is therefore situated at a considerable distance from the arch of the aorta. Should, however, the sac of the aneurysm involve the innominate artery the right recurrent nerve may be implicated, or the trachea may be displaced by an aneurysmal tumour in such a way that its convexity may press on the right recurrent and pneumogastric nerves, causing paralysis of the right vocal cord, or centripetal irritation of the trunk of the left vagus may act on the nervous centre, and through it upon the nerve-supply to the laryngeal muscles on the right side. I have found the combination of complete paralysis of the left vocal cord due to pressure on the left recurrent nerve by malignant disease, together with the existence of valvular disease and enlargement of the heart, extremely difficult to distinguish from an intra-thoracic aneurysm. In some cases it is possible to recognise the direct pressure of an aneurysm upon the trachea by means of the laryngoscope. The bulging forward of the posterior wall can be seen, and with a good light and a tolerant patient pulsation may even be distinguished.

DISEASES OF THE DIGESTIVE SYSTEM.

The possibility of chronic gastric catarrh being kept up by the irritation produced by swallowing fœtid secretion from the nose and naso-pharynx should be borne in mind by the physician who finds that his patient does not readily respond to the usual treatment. Whether as the result of the improvement of the general health or from the cessation of the local cause of irritation, I have noted that symptoms of dyspepsia have disappeared after the nose and accessory sinuses have received attention. That the stomach may be involved secondarily to the upper air passages is pretty generally agreed, but it is not so easy to prove that affections of the upper air passages may occur as a result of stomach derangements. Various theories may be propounded to explain the connexion between affections of the upper air passages and diseases of the stomach. We may appeal to the theory of reflexes or we may attribute to the ubiquitous bacillus the *rôle* of disturbing the functions of remote organs. In speaking of the treatment of granular pharyngitis in my book on "Diseases of the Nose and Throat" I say that "it is most important that attention should be paid to the general health of the patient. If there be any symptoms of indigestion these should be seen to." Further experience has only confirmed what I have therein stated, and I am convinced that the state of the pharynx is much influenced by the condition of the stomach and liver.

DISEASE OF THE LIVER.

In connexion with hepatic diseases I have only to remark that very severe epistaxis is not uncommonly an early symptom of cirrhosis of the liver, the bleeding occurring from dilated veins at the posterior part of the nose. In a middle-aged person the occurrence of epistaxis is almost as suggestive of cirrhosis of the liver as are piles. Hæmorrhages from, and ecchymoses in, the mucous membrane of the pharynx and larynx may be recognised in some cases of cirrhosis and cancer of the liver; also in acute yellow atrophy. A recent development of throat specialism is the doctrine that a varicose condition of the veins at the base of the tongue is one of the objective causes for many subjective throat symptoms of the nature of "globus hystericus." A lengthy discussion which took place in the columns of THE LANCET in the early part of last year has been the means of relegating lingual varix to its proper position. That an enlargement of the veins at the back of the tongue does occasionally exist I am quite ready to admit, but that this condition is "an etiological factor in many obscure pharyngeal and laryngeal symptoms" does not agree with my own observations. I have found that with attention to diet, the administration of saline aperients, and limiting the amount of alcohol taken the patients have speedily improved and have not required any local treatment.

BRIGHT'S DISEASE.

Epistaxis is a frequent symptom of chronic interstitial nephritis and is occasionally met with in the other forms of Bright's disease. It may be quite an early sign of granular kidney; the urine should therefore be examined in cases of abundant or frequent epistaxis. The bleeding is dependent upon the altered blood state, changes in the vessels of the Schneiderian mucous membrane, and upon the cardiac hypertrophy and increased arterial tension. The exact connexion between Bright's disease and œdema of the larynx is still a matter of discussion. The probable explanation is that Bright's disease determines the onset of the œdema in cases in which, under ordinary circumstances, the local irritation would have been too slight to have caused it.

LOCOMOTOR ATAXY.

Nasal conditions associated with tabes are rare. That

[1] Owing to the present great pressure on our space we have been reluctantly compelled to abbreviate this third Lettsomian Lecture. Lectures I. and II. appeared in THE LANCET of Feb. 6th and Feb. 27th respectively.—ED. L.

Hosted by Google

there is hyperæsthesia of the nasal mucous membrane is shown by the fact that laryngeal crises can at times be elicited by irritating the nasal fossæ. In the pharynx both the sensory and the motor nerves may be affected. All varieties of sensorial disturbance may occur—viz., anæsthesia, hyperæsthesia, and paræsthesia. On the motor side there may be paralysis or spasm with contraction. The mucous membrane of the larynx, like that covering the pharynx, may be the seat of anæsthesia, hyperæsthesia, or paræsthesia. On the motor side three kinds of affections are seen in the larynx as a result of tabes—(1) spasm of the adductors; (2) paralysis of the abductors; and (3) incoördination of the laryngeal muscles. The last mentioned of these laryngeal affections of tabes is a true ataxy of the vocal cords, and is perhaps one of the earliest laryngeal signs of tabes.

[Dr. de Havilland Hall here made short references to Syringomyelia, Paralysis Agitans, Labio-glosso-laryngeal Paralysis, and Reflex Epilepsy of Nasal Origin.]

HYSTERIA.

The neuromimetic conditions affecting the upper air passages are so numerous that I can only briefly describe some of the most important. It has been stated that a regular attack of hysteria may be produced by the irritation of certain parts of the nasal mucous membrane, the so-called hystero-genetic zones, and that after the application of the galvano-cautery to these areas the attacks have ceased to occur. Though I have been examining the interior of noses for the last twenty years, and have constantly used the probe, I have never succeeded in starting off an attack of hysteria. The motor neuroses of the pharynx may be due to spasm or paralysis. The so-called globus hystericus is nothing more or less than spasm of the pharyngeal muscles. Hysterical paralysis of the muscles of the pharynx may, by causing dysphagia, give rise to the suspicion of malignant disease, especially if the patient is middle-aged; the diagnosis is readily effected by means of the œsophageal bougie. A curious condition to which the term inspiratory spasm or perverted action of the vocal cords has been applied is occasionally seen in hysterical persons. In this affection the voice remains normal, but on attempts at inspiration the vocal cords, instead of separating, approximate in a convulsive manner. Sometimes they come in contact and cause grave interference with respiration; at other times they remain in the cadaveric position, giving rise to inspiratory stridor. Another form of spasm is the "barking cough of puberty."

NEURASTHENIA AND MELANCHOLIA.

The subject of the various reflex nasal neuroses has received much attention of late years and there has been a tendency, I think, to exaggerate the effect of the various intra-nasal lesions. As I frequently examine the noses of patients—no matter what their complaint—I have come across numerous instances of deflected septa, nasal crests, and spurs in patients in whom there is no symptom of any nasal or reflex nasal affection. On the other hand, there is no doubt that these same conditions in neurotic or neurasthenic patients would produce symptoms of a reflex character curable by local treatment in conjunction with suitable general treatment. Some patients become quite hypochondriacal as to the state of the nose and are constantly craving for an application of some kind or the other to be made to it. I have recently had under my care a lady, forty years of age, who, on account of paroxysmal sneezing, "suffered many things in the way of removal of bone, cautery, &c." She certainly lost the sneezing, but since it disappeared she has suffered from flatulent dyspepsia, acidity, intestinal catarrh, and constipation, accompanied by neuralgia and various sensations referred to the pelvic viscera. She has lost flesh, is terribly depressed, and is a typical example of neurasthenia. She dates all her present symptoms from the time she ceased to sneeze, and attributes them to the shock of the numerous and severe operative procedures carried out in her nose. Her medical man takes the same view, and I am disposed to agree with him.

HEADACHE.

There is hardly any nasal affection but has headache for a symptom. Hence a careful examination of the nose and accessory cavities should be carried out before headache is regarded as being of a neurasthenic or neuralgic origin. Chief among the nasal causes of headache may be mentioned hypertrophy of the turbinals giving rise to nasal stenosis; deflection of the septum may also have a similar effe Furthermore, I should here like to direct attention to the pain referred to the nape of the neck and the occipital region radiating towards the ear, which is met with in some pharyngeal affections.

[Dr. de Havilland Hall here referred briefly to Meningitis, Cerebral Abscess, Cerebral Hæmorrhage, and Epistaxis.]

CONCLUDING REMARKS.

I have purposely refrained from saying anything about diphtheria because the subject is too wide to be treated in an adequate manner in the time I could devote to it. Moreover, it is somewhat outside the limits I laid down for my own guidance when I commenced writing these lectures. For similar reasons I have not discussed the manifestations of tubercle, syphilis, and malignant disease in the nose and throat, as these are well described in the various text-books on the subject. The plan I proposed to myself was to group together the various affections of the upper air-passages as they may occur in connexion with general or local diseases, and also to point out the diseases of remote organs which may arise as a result of affection of the upper respiratory tract. A secondary object I had constantly before me was to accentuate the importance of a systematic examination of the nose, naso-pharynx, pharynx, and larynx. I am quite conscious that I have omitted many points of interest, but the task of selection is rendered difficult by the very abundance of material.

CHRONIC INTERSTITIAL NEPHRITIS IN CHILDHOOD.[1]

BY LEONARD G. GUTHRIE, M.A., M.D. OXON., M.R.C.P. LOND.,
PHYSICIAN TO THE REGENT'S PARK HOSPITAL FOR PARALYSIS; PHYSICIAN TO OUT-PATIENTS AT THE PADDINGTON-GREEN CHILDREN'S HOSPITAL AND THE NORTH-WEST LONDON HOSPITAL.

(*Concluded from page 688.*)

PHYSICAL SIGNS AND SYMPTOMS (*continued*).

Mental characteristics.—Children suffering from this complaint seem to be shrewd, precocious, and intelligent beyond their years. This was noted particularly in Dr. Barlow's fatal case. In my own fatal case there was a peculiar mental perversity. The patient apparently soon discovered that she was an object of interest, and did all she could to attract attention. She would scream incessantly and feign unconsciousness during the friends' visiting hour at hospital, but afterwards would confess that she knew all that was going on. She would beg that poison might be given her and disturb the whole building by her shrieks at night, but would be quiet directly she had succeeded in having the house physician called up to see her. It was difficult to ascertain whether she were actually in pain or only counterfeiting it.

I have observed in other cases that intelligence appears to be above the average. It is possible that the active cerebral circulation in such cases due to cardio-vascular hypertrophy may conduce to premature mental development. There may be more truth than W. S. Gilbert supposed in his ballad concerning the precocious child, who died "an enfeebled old dotard at five."

Cerebral symptoms.—Headache and vomiting were prominent features in four of these fatal cases. In two headaches were frequent, but there is no mention of vomiting. In one vomiting was frequent, but not headache. Vertigo and amaurosis accompanied headache and vomiting in my own fatal case. The localisation of headaches is of no value; it is usually frontal, but may be occipital, coronal, or lateral. They resemble those of migraine in their periodicity, severity, and association with visual disturbance or vertigo, and in being often relieved by vomiting. Also, at first they commonly occur on waking in the morning, as in migraine, though later they may happen at any time of the day. I

[1] A paper read before the Harveian Society of London on Nov. 19th 1896.

Hosted by Google

shall mention presently points by which they may be distinguished from other headaches. As to the cause of headaches in interstitial nephritis, in many cases they are doubtless uræmic, especially when occurring late in the course of the disease. But they may also be produced by alterations in the cerebral circulation, dependent on the increase of arterial tension which prevails. Their occurrence in the early morning may depend on sudden increase of tension in arterioles which have been previously relaxed during sleep. The later or more strictly uræmic headaches may also occur chiefly on first rising, owing to the effect of the accumulation of toxins in the blood during the night.

Vomiting may occur either with or without headaches; it may be independent of food or otherwise. It may be strictly cerebral and, like headache, produced by vascular conditions of the brain. Sometimes it seems to be purely gastric and due to congestion, catarrh, and irritability of the stomach. These are probably the causes in early stages of the disease, whilst late vomiting is, like late headache, dependent on uræmia. There can be no doubt that uræmia occurs far later and is far graver in interstitial nephritis than in parenchymatous.

Albuminuric retinitis might be expected to occur in children as in adults suffering from chronic interstitial nephritis. But it is not mentioned in any of the cases collected, and in my own patients I have never discovered it. Convulsions were prominent in two of the cases; in two they only occurred just before death; in one they were absent, death being due to gradual exhaustion; in one there were attacks of tetany and opisthotonos, after one of which the boy died comatose; and in one, recorded by Dr. Goodhart,[2] there were also attacks of tetany and cramp in the legs, but the subsequent history is unknown to me. Convulsions are, therefore, fairly common in this disease; but they are far more common, they occur earlier, and are more usually recovered from, in cases of parenchymatous than in interstitial nephritis. In adults it is not uncommon to find granular kidneys in a patient who has remained in apparent health until attacked by a series of convulsions during or directly after which he has died.

A point of interest about my own fatal case is that the convulsions were almost entirely unilateral. I do not doubt that they were uræmic, although the right side was chiefly affected. Large hæmorrhages in the right cerebral hemisphere were found after death, which probably, although not directly involving the motor tract, lowered its power of conducting impulses from the cortex downwards. A few days before death there was some transitory left hemi-paresis. Had the convulsions been due to the hæmorrhage, of course they would have affected the left and not the right side. Cerebral hæmorrhage occurred in one of Dr. Dickinson's fatal cases as well as in my own. I have not met with any other cases of hæmorrhage into the substance of the brain due to nephritis in children.[3] Cerebral apoplexy in children from any cause is, indeed, rare. It occurs in cases of purpura, commonly of scorbutic origin, but is usually then meningeal, forming the condition known as pachymeningitis hæmorrhagica. It is rarely intra-cerebral. Sometimes hæmorrhage, either intra- or extra-cerebral, is caused by rupture of miliary aneurysms of the arteries. The aneurysms themselves may be produced by syphilitic endarteritis or by weakening of the vessel wall consequent on embolism or thrombosis. During paroxysms of whooping-cough hæmorrhages into the brain or meninges or elsewhere may take place. In my own case no source of the larger hæmorrhages could be discovered, but one at least of the smaller extravasations was in the neighbourhood of a small thickened arteriole which had apparently burst. The larger hæmorrhages may have been similarly caused. The character of the symptoms rendered it unlikely that they were due to sudden rupture of large vessels.

Some cases of infantile hemiplegia or monoplegia are doubtless caused by hæmorrhage. But they are seldom fatal at the time, and when death occurs many years later all traces of hæmorrhage have disappeared, or else cysts may be found which may or may not have been hæmorrhagic in origin.

The intestinal symptoms are not peculiarly distinctive of interstitial nephritis. Sometimes the appetite is capricious or enormous, and, as already stated, there may be extreme thirst. Diarrhœa, like gastric vomiting, may be dependent on catarrh or irritability of the bowels. It is provoked by the slightest indiscretion in diet. The motions are slimy, mucous, or frothy, and at times contain blood. There may be epigastric or abdominal pain. The attacks are soon over as a rule, but when obstinate and of long standing one must suspect the occurrence of albuminuric ulceration of the bowels. Sometimes constipation alternates with diarrhœa. One of Dr. Dickinson's patients suffered before death from purulent peritonitis. I have only seen one instance of this complication. But this was in a child, aged four years, who died from general dropsy and uræmic convulsions. Parenchymatous and not interstitial nephritis was found after death, and the kidneys contained abundance of uric acid crystals. Probably peritonitis in children, as in adults suffering from chronic nephritis, occurs in a proportion of about 10 per cent. It was found in 46 out of 406 cases collected by Sir William Roberts.

Urinary symptoms.—Polyuria was noted in four of the fatal cases, as much as three, four, or even five pints of urine being passed per diem. It is probably an early symptom in all cases, but is not likely to attract attention unless, as in Dr. Barlow's patient, it is associated with enuresis. Even in adults suffering from granular nephritis the symptom is rarely made the subject of complaint—in fact, it is usually regarded as a favourable sign that urine is passed freely; diminution in quantity, on the other hand, both in the child and adult, at once excites alarm. The amount, however, shows considerable variations, and when at its lowest eclampsia is wont to occur. In my own fatal case the average amount of urine passed per diem was forty-eight ounces, but on the two days on which fits occurred the amount fell to twenty-five ounces and eighteen ounces. On the days immediately succeeding the fits the amounts were fourteen ounces and eighteen ounces, whilst on the second days following the fits the quantities rose to eighty-four ounces and 106 ounces respectively. A similar reduction in quantity of urine in association with eclampsia is noted in two other cases. Generally speaking, there is something to be said for the popular view that polyuria is a favourable sign, indicating as it does the completion of cardio-vascular compensation. Naturally, the greater the quantity of urine the greater the elimination of toxins. It is none the less an important symptom of a grave disease. Polyuria was associated with thirst in three of the fatal cases.

The specific gravity is generally low. In my own fatal case it was almost invariably 1010, occasionally 1008, and once only reached 1015. In two other cases, where it is mentioned, the specific gravities were 1004 and 1005 respectively, whilst in a third it varied between 1010 and 1020. It does not appear to be influenced by the amount of urine passed to any great extent. In my own fatal case it was 1010 when 106 ounces were passed in twenty-four hours, but only 1015 when the amount was fourteen ounces. Whilst Dr. Barlow's patient was passing from four to five pints of urine a day the specific gravity was 1015, and it only rose to 1020 when the amount had declined to three-quarters of a pint.

The albumin varies greatly in quantity. It may be entirely absent at first. Generally speaking, the amount is not large—or not so large as in cases of parenchymatous nephritis. In one only the urine is said to have become at times almost solid on boiling. This occurred during attacks of vomiting and tetany, when, instead of the usual polyuria, there was marked scantiness of the urine.

Casts in the urine are rare. They are usually of the hyaline variety, but sometimes are granular. Blood casts may occur in association with the acute exacerbations already mentioned in the course of the disease. Ordinarily there is seldom abundance of any deposit. The urine generally is clear, pale, and acid.

No statement is made as to the percentage of urea in any of these cases. In all probability it would have been found reduced below normal. To avoid fallacy it is worth remembering that children normally pass a larger relative quantity of solid matter than adults. (According to Dr. Eustace Smith the average amount passed by a child is five grains for each pound of body weight. In the adult Dr. Parkes estimates the amount as 3½ grains per pound weight.)

Pulmonary symptoms.—Children suffering from interstitial nephritis are often subject to recurrent attacks of bronchial catarrh as well as of gastro-intestinal catarrh, and may first be seen on this account. They are often somewhat breathless after exertion, but the dyspnœa is not usually extreme

[2] Keating's Encyclopædia of Children's Diseases.

[3] A third case has been reported by Filatoff in a child aged eleven years. (Emmett Holt: Diseases of Children, 1897, p. 621.)

Hosted by Google

except in the last stages of the disease, when pulmonary œdema is common. In adults the recent occurrence of attacks of spasmodic asthma in a patient who is not a typical asthmatic and who does not suffer from chronic bronchitis or heart disease suggests uræmia. Such attacks when uræmic are of extemely fatal augury. Asthmatic attacks, however, are not necessarily uræmic; the speedy relief afforded by nitrite of amyl suggests that they may be due to constriction of the pulmonary arterioles in some cases. I have not met with them in children suffering from interstitial nephritis. But my experience is limited; and as the symptoms in children in other respects precisely resemble those of adults, it is probable that children also might suffer from asthma. In adults suffering from granular kidney, pleurisy, pleuro-pneumonia, and pericarditis commonly end the scene. I have not met with such instances in children, nevertheless they may doubtless occur.

Cardiac symptoms are not obtrusive. There may be slight præcordial pain or distress on exertion. In two of my cases these were amongst the first symptoms which arose. Probably slow cardiac hypertrophy is unattended by symptoms unless it is on the point of failing.

ETIOLOGY OF CHRONIC INTERSTITIAL NEPHRITIS.

Once it was thought that all granular kidneys were simply large white kidneys in their final or contracted stage. But this cannot be so in all cases, because a large white kidney sufficiently diseased to end in contraction must have been attended by definite symptoms of severe illness, including dropsy. Yet the majority of those who die with granular contracted kidneys have not been severely ill until shortly before death and are said never to have had dropsy, and dropsy is not a condition which can be readily overlooked.

Possible scarlatinal origin.—One naturally thinks of scarlet fever in these cases. This is undoubtedly the origin in some, but in the majority there is no history of scarlet fever. Mild scarlet fever may easily escape recognition, it is true, and so may subsequent desquamation and also slight attacks of nephritis. But attacks of scarlet fever so mild as to escape recognition at the time are hardly likely to be followed by lasting progressive and finally fatal renal mischief. Even in the worst cases of undoubted scarlatinal nephritis the prognosis is generally good. Children very rarely die from it. And if the prognosis is good in the worst cases it must be better in the mildest. Otherwise, the milder the initial fever the more hopeless would be the prospect. Scarlet fever cannot be regarded as the cause of all cases of interstitial nephritis, though doubtless it is so in some.

The character of the nephritis.—Is the nephritis of an ascending character due to previous bladder trouble or obstruction of the ureters or exit of the bladder? In my own fatal case and also in the two recorded by Dr. Dickinson the kidneys were very unequal in size and the pelvis or upper part of the ureter connected with the smaller kidney were found somewhat dilated. In one of Dr. Dickinson's patients a vesical calculus had been removed many years before death, and he suggests that in both cases there may have been some bygone obstruction to the exit of urine, although no actual obstruction was found after death. Dr. Goodhart[4] was struck by the cases he had himself seen and by those recorded by others, in which a shrunken kidney was found with a dilated pelvis. He regarded the latter condition not necessarily as a proof of obstruction, but possibly merely an indication of atony of the ureter. At the same time he held that impaction of small calculi in the ureters was not uncommon in children. This is indisputable, but it is difficult to see how impaction of a calculus in one ureter should produce interstitial nephritis in both kidneys. For the affection of the two kidneys only differed in degree, and not in kind. Yet I am inclined to think that the dilatation of the ureter on the side of the kidney most contracted (though not the nephritis) may be dependent on obstruction brought about as follows: Polyuria is a marked symptom of granular nephritis. The result of this would be more or less constant fulness of the bladder with a certain amount of backward pressure in the ureters. Now if granular kidneys secrete more water than normal it follows that the more granular the kidney the more water it will secrete. Hence if any obstruction to the entrance of water into the bladder is occasioned by distension of the latter it follows that the obstruction will be most felt by the kidney which secretes most water. We may therefore get dilatation of the ureter on the side of the most contracted kidney. However, such obstruction would be secondary to nephritis, and not its primary cause.

Cystitis.—As regards their dependence on cystitis, no mention of the bladder is made in any of the cases which I have quoted, and I can only assume that it was healthy in all, as it undoubtedly was in my own.[5] Hence I must regard all the cases as being interstitial nephritis of primary nature. Dr. Dickinson gives as the causes of granular kidney gout, lead, alcohol, cardiac changes leading to renal congestion, pregnancy, obstructional anuria, mental conditions, worry, &c., perhaps intermittent fever, and "a general fibrotic tendency affecting many organs and tissues, notably the arteries and kidneys." The last I have already referred to in the section on cardiac vascular changes. Lead and alcohol may be excluded in all the children to whom reference has been made. Of the other causes we may dismiss without discussion all but the first—namely, "gout," or rather uric-acidity, which may be regarded as the equivalent of gout, in childhood.

Uric acid nephritis.—Children who have what is termed the uric acid diathesis often suffer from attacks of pain referred to the loins or especially the sites of the ureters or bladder. These attacks are commonly associated with headache or gastro-intestinal disturbance. The urine is usually highly acid and of high specific gravity, irritating, and small in quantity. It contains abundant crystals of uric acid or oxalates. Often there are intermittent attacks of hæmaturia, hæmoglobinuria, or albuminuria. It is believed that the urinary symptoms are due to the passage of sharp and lacerating crystals of uric acid or oxalates through the urinary tracts, and it is certainly conceivable that a long continuance of such irritation might lead to diffuse nephritis. Dr. Eustace Smith[6] says: "In a case where a child habitually passes large quantities of uric acid I should be disposed to fear the occurrence of Bright's disease; and the occasional presence of a trace of albumin would add strength to my apprehensions." My own experience of such cases, which are common enough, is that the patients speedily get well so far as the urinary symptoms are concerned under very simple treatment. They are, however, prone to run the whole gamut of rheumatic affections, such as tonsillitis, pericarditis and endocarditis, chorea, arthritis, and peliosis. I am inclined to think that the occasional presence of blood, free or in casts, and of albumin, are purely accidental in uric acid cases, and are due, as I have said, to slight renal laceration, and are not to be taken as evidence of nephritis.[7] In none of the fatal cases of interstitial nephritis which I have collected was the passage of uric acid a feature, and in none of them is there mention of the occurrence of rheumatic symptoms. I would therefore regard cases of so-called uric acid nephritis as in a totally different category to that of true interstitial nephritis.

Primary cause of granular kidney.—Dr. Emmet Holt[8] has collected twenty-three cases of primary nephritis in infants aged between two and a half months and two years, and of these eleven were fatal. Post-mortem examinations were made in ten. In five the kidneys showed ordinary parenchymatous nephritis, but in the remaining five the conditions found were regarded as those of acute interstitial nephritis characterised by infiltration of the renal stroma by small cells in scattered areas, with sometimes formation of new connective tissue. These cases, verified by post-mortem examination, prove that young infants may suffer from an acute form of interstitial nephritis. The characteristic lesions were found in one case after an illness of only three days' duration, in some after the disease had lasted several weeks. The symptoms are mainly gastro-intestinal, such as vomiting, diarrhœa, or looseness of the bowels. In many there are marked cerebral symptoms, restlessness, screaming, convulsions, drowsiness or coma, as in meningitis. High fever is common, and hyperpyrexia may occur. The symptoms are not characteristic of nephritis. Dropsy was absent in all the fatal

[4] Keating's Encyclopædia of Children's Diseases.

[5] In the Transactions of the Pathological Society, 1896, I have reported the case of an infant, aged ten weeks, in whom suppurative interstitial nephritis with dilatation of the ureters were caused by congenital malformation of the bladder and consequent cystitis.

[6] Diseases of Children, p. 757.

[7] It must be admitted that most forms of nephritis may be associated with the passage of uric acid in the urine, and after death in such cases uric acid may be found in the kidneys. Whether the uric acid is the cause of the nephritis, or only a product of disordered metabolism, dependent on the nephritis, must be left an open question. Many people pass large quantities of uric acid for a considerable portion of their lives, and appear, like birds and reptiles, none the worse for doing so.

[8] Archives of Pediatrics, 1897 vol. iv., p. 1.

Hosted by Google

cases in which interstitial nephritis was found. The condition of the urine may or may not afford a clue to the nature of the disease. The urine may often be suppressed or scanty and of low specific gravity. Albumin was found in eight of Dr. Holt's cases, in one of them only three days before death, the illness having lasted more than two weeks. In one it was only found in the bladder after death. Casts (blood and hyaline) were present in four cases. Blood and pus were present in two.

As to the causation of acute interstitial nephritis.—Scarlet fever may be fairly excluded. Dr. Holt regards its existence as non-proven in all his cases. There is no evidence that any of these were cases of secondary or ascending nephritis or that the inflammation was syphilitic or tuberculous. Primary parenchymatous nephritis, when not scarlet fever, is usually held to be due to exposure to cold. Dr. Eustace Smith draws attention to the custom of short-coating babies at an early age and thus leaving them practically naked below the armpits and exposed to chills. He regards this practice as the possible cause of infantile parenchymatous nephritis, and, if so, it may also account for the interstitial form of the disease.

It might be thought that the deep situation of the kidneys in the body would afford them protection against the effects of chill to the surface of the skin. But mere depth of covering cannot render them immune any more than other organs. Otherwise, the obese would lead a charmed life. There can be no doubt that exposure to cold will produce nephritis in one person just as in others; it may be the exciting cause of tonsillitis, acute rheumatism, pneumonia, pleurisy, or hepatitis. Probably in all cases chill to the surface vitiates the functions of the blood, thus causing either actual generation of toxins or hindrance to their elimination, or perhaps imperfect phagocytosis. The organs which are weakest in the individual will be those to suffer. We cannot predict whether it will be his tonsils, his lungs, his liver, or his kidneys, or explain why one organ should be attacked rather than another. If all are sound he may escape all ill effects. The nature of the poisons generation or non-elimination of which cause inflammation of the kidneys, as well as that of the poisons which are retained in the system in consequence of nephritis, remain unknown at present.

Granting the existence of a primary interstitial nephritis caused by chill, we can well believe that in such cases as recover from the immediate effects new connective intertubular tissue may gradually become contracted and produce in time the characteristic appearance of granular kidney. This may account for cases of renal cirrhosis of long standing even in adults in whom evidence of the other causes enumerated is wanted.

SUMMARY.

Diagnosis.—In some cases the diagnosis presents no difficulty. We must suspect the existence of interstitial nephritis in a child who is emaciated, whose skin is coarse, dry, inelastic, and pigmented; who suffers from uncontrollable periodic attacks of vomiting, vertigo, and maddening headaches. Then if we find the heart's apex displaced outwards, the left ventricle hypertrophied, the second sound accentuated, the pulse hard, the urine of low specific gravity, increased in quantity, and albuminous, the diagnosis of interstitial nephritis is complete. Yet in such a case the disease is already far advanced and the end is not far off. It is characteristic of the complaint, both in adults and children, that the symptoms do not attract attention until there can be but little hope of recovery. Hence it is of the greatest importance to discover the disease in its earliest stages. Probably wasting, gradual and progressive, is the first symptom to occur. Polyuria and thirst are also early symptoms. The first indication of polyuria may be enuresis. Pigmentation is also an early sign, though it may amount only to mere sallowness at first. A patient suffering from interstitial nephritis never looks well, although he may not complain of any symptoms. Headache, vomiting, and diarrhœa may not occur until the disease is well advanced. In all cases when suspicion of nephritis is aroused one examines the skin for dryness, coarseness, inelasticity, and pigmentation, the heart for incipient hypertrophy, the pulse for hardness, the urine for low specific gravity and albumin. When one or more of these conditions are absent others may take their place. Pigmentation may be wanting or slight in degree, but anæmia, with rough, dry skin, will be found. On the other hand, pigmentation, when the skin remains moist, smooth, and supple, is rather suggestive of true Addison's disease than of adrenal disease secondary to Bright's. But in true Addison's disease the heart is not hypertrophied and the pulse remains feeble and soft throughout, whereas in interstitial nephritis cardio-vascular hypertrophy and high arterial tension are almost universal. Yet cases of interstitial nephritis may run their course without apparent thickening of the heart or vessels. When this is so there may still be albuminuria to guide us. With cardio-vascular hypertrophy are usually associated headaches, increasing quantity and low specific gravity of the urine, but there may be no albumin. In adults, when compensating cardiac hypertrophy fails and gives way to dilatation, the urine usually is reduced in quantity, becomes albuminous, and dropsy appears. But in children suffering from interstitial nephritis dropsy is very rare, yet it may occur and may be the first symptom, together with scanty, smoky, and albuminous urine which draws attention to the disease. The condition of the skin and vascular system will serve to distinguish such attacks from those of ordinary acute nephritis. The differential diagnosis in these cases is most important. The absence of albumin, even after frequent and systematic testing, does not exclude the possible existence of the disease. Albumin may only occur occasionally or not till late. Hence the importance of frequent and systematic testing for its presence.

History of infantile nephritis.—Some help towards the diagnosis may be gained from a past history of a tedious gastro-intestinal complaint in a child who has remained emaciated, cachectic-looking, and with easily disturbed digestion ever since. The significance of violent periodic headaches, especially if associated with vomiting or vertigo, and occurring in the early morning, is very great. Like convulsions, they may not appear until the last stage of the disease is at hand, but whenever they do occur urinary symptoms or cardio-vascular changes will almost certainly be present to aid the diagnosis. The somewhat similar attacks due to cerebral tumour may be distinguished from them by being less periodic than chronic, with exacerbations and by the presence of optic neuritis. Probably there will also be other nervous symptoms and conditions, such as paralysis or focal epilepsies, which will make the diagnosis of tumour certain. Wasting is in cases of cerebral tumour rare, except in the latest stages, unless the tumour is part of general tuberculosis; whilst in interstitial nephritis it is, I believe, universal. Headaches due to local conditions of the eyes, nose, throat, ears, and teeth are easily identified. Headaches due to simple anæmia, constipation, and general debility require no comment. Migraine headaches may at times be difficult to distinguish from those of interstitial nephritis, but they are unaccompanied by permanent cardio-vascular and urinary changes. Uric acid headaches may resemble those of interstitial nephritis, and the diagnosis may be further obscured by the occurrence of temporary attacks of hæmaturia and albuminuria and also by the cardiac enlargement often present in those of the so-called uric acid diathesis. But the presence of uric acid or oxalate crystals in the urine sufficiently accounts for the hæmaturia and albuminuria and does not *per se* indicate interstitial nephritis. The enlargement of the heart dependent upon valvular disease or pericarditis met with in uric acid or rheumatic cases may be distinguished from that which forms part of the cardio-vascular changes of interstitial nephritis by the presence or history of other rheumatic signs and symptoms, such as tonsillitis, arthritis, appendicitis, peliosis, and chorea.[9] The distinction is important, especially in the case of pericarditis, as this complication is, I believe, speedily fatal in adults suffering from granular kidney, and would probably be so in children, whereas the immediate prognosis of ordinary rheumatic pericarditis in children is fair. Pulmonary symptoms in the interstitial nephritis of children are probably the same as in adults. Slight dyspnœa and attacks of bronchial catarrh may first lead the patient to seek advice. Pulmonary œdema in late stages of the disease may mark the onset of uræmic convulsions. In either case the patient's appearance, heart, pulse, and urine will serve to distinguish such attacks from those of the ordinary pulmonary affections of childhood. Finally, it may be said that the symptoms of interstitial nephritis are as

[9] The permanence and fixed locality of the bruits in ordinary valvular disease will distinguish them from the temporary and shifting murmurs met with in commencing failure of the hypertrophied heart in interstitial nephritis.

Hosted by Google

insidious and gradual as the morbid process itself. In many cases we can only suspect the existence of the disease. It may be months or even years before such suspicions prove to be well founded or set at rest.

Prognosis.—Interstitial nephritis may go on for many years without causing the patient or his friends to think there is much amiss. The typical granular kidney must require a very long time to arrive at its condition. It is even possible that in an adult it may date from an attack of acute interstitial nephritis occurring in infancy. Yet the duration of the symptoms of which complaint is made rarely exceeds a few years, and may be only a matter of months or even weeks In one of the fatal cases collected symptoms had lasted three weeks. In two the duration was three months, and in three symptoms had been observed for two, three, and five years respectively. As I have endeavoured to show, the effects of cardio-vascular hypertrophy are to avert, or at all events to compensate, for those of renal disease. Dropsy is reduced or is prevented by the circulatory changes, and uræmia by the polyuria which occur. Cardio-vascular compensation attains its height in interstitial nephritis, and the onset of symptoms depends to a great extent (1) on the failure of such compensation, and (2) on its being carried to excess. In adults failure and dilatation of the heart and degeneration of the bloodvessels are often the chief causes of the fatal symptoms. But in children and also in adults they may be actually due to excess of cardio-vascular compensation. Thus may be produced the violent headaches for which advice is often first sought. Extremely high general tension due to constriction of arterioles, combined with a powerfully acting heart, may cause hæmorrhage or cerebral apoplexy. Constriction of pulmonary arterioles may give rise to dyspnœa, asthma, or pulmonary apoplexy, or in the extremities it may cause Raynaud's disease or gangrene, whilst constriction of renal arterioles when carried to excess may, instead of increasing the amount of urine, actually reduce it, and so bring about uræmia as well as further damage to the kidneys. So the prognosis will largely depend on the degree at which cardio-vascular hypertrophy is maintained and on our ability to aid or thwart its progress as required. Bad signs will be commencing heart failure, headaches, vomiting, dyspnœa, with diminution of urine, increasing albuminuria, progressive wasting, and pigmentation. It is needless to point out that the prognosis will be more grave when symptoms of Addison's disease are superadded to those of interstitial nephritis. The surroundings of the patient and his liability therefrom to chills and consequent inflammations so often fatal in this disease must be considered in the prognosis. Finally, although the conditions of heart, pulse, skin, and urine make the existence of the disease evident, life may not be endangered unless signs of failing or of excessive cardio-vascular compensation arise. In the first case the child is no better off than the adult—both are doomed; but in the second case treatment may ward off danger for the time.

Treatment.—The treatment is symptomatic rather than curative; yet it is rational and follows the lines of pathology laid down. In parenchymatous nephritis, when dropsy threatens or is present and cardio-vascular hypertrophy is slow to occur and at first insufficient, we give digitalis, squill, and citrate of caffein, which are not only powerful heart tonics, but also have a constricting effect on the arterioles and thus promote diuresis. The utility of ergot and cantharides may be similarly explained. Citrate and acetate of potash become converted into alkaline carbonates in the "primæ viæ," and Brunton, Cash, and Gaskell [10] have shown that the effect of alkalies is to contract bloodvessels, whilst that of acids is the reverse. Bi-tartrate of potash is also a remote antacid. If it be true, as I have contended, that dropsy is averted or cured by constriction of arterioles and increased cardiac force, we can understand that the use of such drugs is rational. In interstitial nephritis, on the other hand, cardio-vascular compensatory hypertrophy is carried out to perfection, and this, together with consequent polyuria, prevents dropsy and also uræmia from occurring. Hence these drugs—cardio-vascular tonics—are not called for in interstitial nephritis, unless cardio-vascular compensation fails. But it must be admitted that nature's endeavours to cure are at best imperfect. Cardio-vascular hypertrophy may be carried to excess in interstitial nephritis. Thus may be produced headaches or even apoplexy by rupture of vessels owing to excessive tension, dyspnœa and possibly asthma by constriction of the pulmonary arterioles, Raynaud's disease and gangrene by constriction of the arterioles in the extremities, and, above all, uræmia by suppression of urine due to constriction of the renal arterioles. The treatment commonly followed in such cases is rational. We lower arterial tension and relieve the heart by giving vascular depressants such as nitro-glycerine, nitrite of amyl, nitrites and nitrates generally; we promote elimination from the skin by warm or vapour baths, liquor ammoniæ acetatis and other diaphoretics, and from the bowels by hydragogue cathartics. Similar treatment is followed in cases of parenchymatous nephritis where pulse tension is high and the heart threatens to give way owing to the obstruction in front. This is the "cardio-vascular depressant" as opposed to the "cardio-vascular excitant" mode of treatment. It is logically combined with catharsis and diaphoresis. So the treatment of interstitial nephritis in some cases consists in counteracting the effects of excessive cardio-vascular hypertrophy and at the same time promoting the action of the skin and bowels in order to compensate for deficient elimination through the kidneys. In the later stages of interstitial nephritis, however, the whole system of cardio-vascular compensation tends to fall through, and then we must have recourse to the cardio-vascular excitants which are so useful in the early stages of parenchymatous nephritis. Possibly when supra-renal inadequacy is indicated by the presence of pigmentation, treatment by supra-renal extract may be of use, and this extract has also an extreme power of constricting vessels, which therefore may be beneficial in another way. The general conduct of the case aims at prevention of complications arising from chill by supplying suitable clothing and, if possible, climate. As to other complications: iron is always necessary to combat progressive anæmia; dyspepsia due to gastric congestion and irritability is best treated by bismuth, arsenic, and prussic acid; eclampsia may be checked by inhalation of chloroform or by rectal injection of chloral and bromides. Headaches may also be relieved by the latter taken internally, but free purgation is the most rational mode of treatment. Venesection is, I believe, both useless and dangerous in the late eclampsia of interstitial nephritis in children. Catharsis and diaphoresis are the best methods of depletion. Dry-cupping, however, may be useful in pulmonary œdema, pleurisy, and pericarditis. Finally, no drug can cure a damaged kidney. Sooner or later the morbid process going on must end in death. Treatment at best can only be palliative, yet by it we may hope to stave off the evil day, and I am convinced that the guiding principle should be—"Watch the heart and pulse."

A REVIEW OF THE OPERATION FOR EXCISION OF THE KNEE, TOGETHER WITH AN ACCOUNT OF A NEW PROCEDURE—OSTEOPLASTIC EXCISION OF THE KNEE.[1]

BY C. B. LOCKWOOD, F.R.C.S.ENG.,
ASSISTANT SURGEON IN ST. BARTHOLOMEW'S HOSPITAL, SURGEON TO THE GREAT NORTHERN HOSPITAL.

IN this communication I propose to describe an operation for excision of the knee which I have performed on several occasions since 1889. Although the operations are not numerous, yet they are enough to show that the proceeding is quite practicable. Moreover, I hope to prove that it has certain advantages over the usual operation. At the outset it is to be understood that it is not to be done in every case of tuberculous arthritis of the knee. On the contrary each should be treated on its merits, and with regard to the kind and degree of the disease, and to the condition and environments of the patient. Thus, during the past ten years I have treated tuberculous arthritis of the knee by rest and local applications, by drainage, by arthrectomy, by the

[1] A paper read before the Medical Society of London on March 8th, 1897.

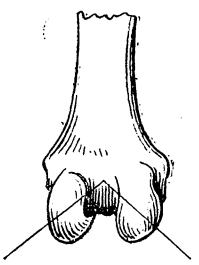
Hosted by Google

ordinary excision, and by the operation which I am about to describe. The last was done upon cases of progressive tuberculous arthritis with pulpy synovial membrane and ulceration of cartilage, but with little caries or displacement of the ends of the bones. Before deciding to operate every effort was made to allay the disease by rest and local applications. But it is important not to delay until sinuses have formed. In the last case a sinus had formed, and the operation was followed by a severe outbreak of septic inflammation. As with most new attempts, errors have been made and failures have occurred. All of these will be clearly pointed out for the guidance of anyone who may be encouraged to imitate my example.

The method of excision which I always see performed, and which is described by all our more recent writers,[2] has certain faults which can be overcome. To these are attributable some of the ill results by which it is not infrequently followed. For instance, during the last few years I have had three times to remove wedges of bone to straighten limbs which had become flexed and rotated after the knees had been excised by the ordinary method. That operation is briefly as follows. A flap of skin and subcutaneous tissue is lifted from the front of the knee by a curved incision; then the capsule and the internal and external lateral ligaments are divided and the patella is taken away, with division of its ligaments; next, the crucial ligaments are cut and a slice or slices of the articular ends of the femur and the tibia sawn off; and, in addition, the synovial membrane is taken away. Abroad von Esmarch,[3] von Bergmann,[4] and others[5] describe the same operation, as do also Ollier[6] of Lyons and Farabeuf.[7] A number of others have been described, but as a rule they only differ from one another in the way in which the joint is opened or in the treatment of the patella. Farabeuf[8] gives no less than six different incisions, and others might be added. However, no operation seems to enjoy the same repute as that which I have just sketched and called the usual operation.

With regard to the ordinary operation I would remark that the mere skin incision is of small importance, provided it fulfils the first of the principles upon which the operation is founded and therefore permits the whole disease to be removed. Sometimes I have used the so-called antero-internal vertical incision of Langenbeck,[9] because it seemed to give better access to the supra-patellar pouches and to spare the patella and its ligament. But it was found to have the disadvantage of not thoroughly exposing the posterior angles of the joint, especially that behind the outer condyle. So of late the transverse or semilunar incision has been used. But the indiscriminate removal of the patella is a much more serious matter. It brings about the destruction of the attachments of the quadriceps extensor femoris and is one of the main causes of the flexion to which I have just referred. As Sir Charles Bell has pointed out, a peculiar harmony pertains to the contraction and relaxation of opposing groups of muscles. When one group is weakened or destroyed the other being unopposed distorts the limb. Sometimes the patella may be too diseased to be kept, but even then the aponeurosis over it and at either side of it can be preserved. When the patella is sound it ought to be kept for another reason. In one case I was able to peg its sawn surface to the joints of the tibia and femur, both of which had been sawn to receive it. The ligaments, too, perform important functions. In extension of the knee, as is well known, they are all on the stretch and keep the femur and the tibia in the closest contact and prevent rotation. The crucial ligaments are particularly important. They obviously prevent displacement of the tibia backwards and forwards. Also, in extension, as Bruce Young[10] has shown, they screw home and lock the tibia and femur. The lateral ligaments assist the crucial ligaments and combine with them to bring about that rigidity and immobility for which the extended knee is remarkable. Obviously in the ordinary operation all this is quite ignored. The shape of the articular ends of the femur and tibia are accessory to this screwing home and locking. And, in addition, the spine of the tibia, being fitted into the intercondylar notch of the femur, effectually prevents lateral displacement of the tibia when the knee is extended. It is hardly necessary to say that the usual operation of resection of the knee sacrifices all the advantages which may be secured by leaving the patella and its ligament, the lateral ligaments, and the crucial ligaments, or by preserving the interlocking of the articular ends. Moreover, it leaves bony surfaces which, besides being unsupported by ligaments, are themselves flat and smooth and easily displaced.

To obviate the disadvantages of the usual operation and to retain the advantages which the arrangements of the ligaments and articular ends afford I have, in suitable cases, performed the following operation. First, the knee being bent at half a right angle, a transverse or slightly curved incision is carried across the centre of the ligamentum patellæ, from one tuberosity of the femur to the other. The ligamentum patellæ is divided and the joint opened. As I have already said, opening the joint by the vertical incision at the inner side of the patella was tried, but was given up because it made the removal of all the synovial membrane difficult or perhaps impossible. This quite outweighs the advantages of the vertical incision. Some surgeons have exposed the interior of the knee by sawing through the patella. But this was not done in any of the cases, because that bone is often tuberculous and because it does not unite with so much certainty as the ligament. Moreover, the divided patella is not adapted for fastening to the tibia and femur. The knee-joint having been freely opened and bent to a right angle the extent of the disease is ascertained. Then the synovial membrane is removed with knife and scissors as carefully as if it were full of malignant disease. Sometimes to get at the upper part of the synovial membrane the ends of the transverse incision have had to be carried upwards. If any synovial membrane be left behind tubercle is likely to grow in it; also it is apt to inflame and secrete fluid which may accumulate and become septic. In removing the synovial membrane it is convenient to leave the part behind the condyles until the femur has been sawn. As the synovial membrane is taken away the ligaments come into view. Healthy ligaments are to be preserved. Whether it is always right to keep both the crucial ligaments remains to be seen. It is certainly very hard to remove all the synovial membrane without cutting the anterior. Nevertheless, as I have pointed out, the crucial ligaments help very powerfully to hold the tibia and femur together; the posterior one prevents the tibia falling backwards as the leg lies extended on the bed; after the ordinary excision there is a tendency for the tibia to fall backwards. Fortunately the posterior crucial ligament can often be preserved and is of service in preventing that accident. The anterior crucial ligament prevents displacement of the tibia forwards, and is therefore less important; it has hardly anything to do with backward displacement. But it would be better to destroy one or both crucial ligaments rather than leave any diseased synovial membrane behind. This was shown by a case in which my anxiety to preserve the crucial ligaments led me to leave behind some synovial membrane which quite spoilt the operation. The patient was a sailor with tuberculous disease of the knee. The disease in the synovial membrane was extensive with considerable ulceration of the articular cartilages. The ligaments were kept; the wound healed by first intention, and he went in six weeks to a convalescent home with the limb in plaster. He had, of course, strict injunctions not to walk on the leg. A month or so afterwards he came back and complained that his leg hurt him when he walked about on it. It was clear from the swelling that the tuberculous process was still progressing, although the union was wonderfully firm considering what he had been doing. My colleague, Mr. Peyton Beale, in my absence, kindly removed the tuberculous disease, which he told me was quite at the back of the joint, behind, I believe, the crucial ligament. The ultimate result in this case was highly satisfactory.



The internal and the external lateral ligaments, being outside the joint, are much easier to save. In the next stage of the operation, after the femur and the tibia have been sawn, these ligaments are of the greatest use in keeping the bones firmly together. So far the operation

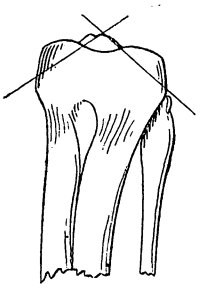
Hosted by Google



has hardly differed from many others; but in the next step—namely, the treatment of the bones—it is quite different from any I have been able to find described. First, the articular surface of the patella is sawn off and, if necessary, its cancellous tissue is gouged. Then the trochlear surface of the femur is sawn off, leaving a flat surface upon which the upper part of the patella fits. The femur itself is next raised vertically by the assistant and the greater part of its articular surfaces taken away by two saw cuts which begin at the convexity of the condyles at the edge of the articular cartilage. These saw cuts are carried obliquely into the intercondylar notch of the femur until they converge, entering the notch at the edge of the articular cartilages and below the attachments of the crucial ligaments (*vide* Fig. 1). In making these cuts the lower part of the rather extensive attachment of the crucial ligament cannot always be saved, but as the upper attachments spread out a good deal the greater part can be saved. The antero-posterior plane of these cuts should be at right angles to the axis of the femur. By these saw cuts a deep notch is made in the femur, leaving some articular cartilage in the front and back of the condyles. This cartilage is either torn off or removed with a sharp spoon or gouge. The tibia is treated upon the same principles as the femur. With a narrow saw two oblique cuts are carried upwards from the epiphysial line to converge at the base of the spinous process (Fig. 2). Here, again, the articular cartilages can be removed

FIG. 1.

Showing section of femur.

FIG. 2.

Showing section of tibia.

without destroying the lower attachments of the crucial ligaments. This is quite feasible because these structures occupy but a small area of the upper surface of the tibia in front of and behind the spine; indeed, the posterior is attached to the posterior surface of the tibia in the popliteal notch. This stage of the operation is easily accomplished without destroying the lower attachments of either the external or of the internal lateral ligaments, the latter being attached down the shaft of the tibia quite out of harm's way. The antero-posterior direction of the plane of these saw cuts is at right angles to the axis of the tibia; their obliquity should correspond to that of the sawn surfaces of the femur.

The advantages which may be claimed for this method of sawing the femur and tibia are as follows. The original fitting of the tibia into the intercondylar notch is preserved and any lateral displacement of the tibia is still impossible. Further, the same wedging in of the tibia effectually prevents rotation of that bone upon its long axis, and, therefore, the foot falls neither inwards nor outwards. To these advantages may be added that large areas of sawn bone are brought in apposition, and this with the smallest removal of either epiphysis. The whole thickness of the femoral epiphysis is left at either side and the whole thickness of the tibial in the middle. If the knee be extended after the bones have been sawn, the benefit of preserving the ligaments becomes apparent. As the leg is extended they become tight and jam the wedge of the tibia into the notch in the femur. Here it is firmly fixed so long as extension is maintained. As I have pointed out, if the crucial ligaments can be preserved a further advantage is gained, because in extension the posterior prevents the tibia falling backwards and the anterior prevents its displacement forwards. The operation is finished by sewing together the ligamentum patellæ with buried silk sutures and by subsequently closing the wound. In one case the patella was fastened with ivory pegs to the femur and tibia, but lately this has been omitted. The patella seems to form very strong connexions without the pegging. The front of the tibia and the front of the femur were wired together in one case so as to prevent flexion. Afterwards the limb is kept for a month or six weeks on a Gant's splint. But after this operation the immobility which is so essential for success is much easier to preserve. Indeed, as the tibia cannot slide to either side or backwards and cannot rotate, we have only to guard against flexion. That movement is one of the easiest to prevent and has little tendency to occur if the patella has been preserved and its ligament sutured. When the limb comes off the Gant splint it is put into a leather splint. A patten having been put on the sound foot the patient goes about on crutches swinging the resected limb. I have hitherto advised that this treatment be continued for a year, but perhaps this time might be shortened.

I have been unable to learn that any surgeon has performed a resection of the knee at all similar to that which has just been described. Mr. Treves[11] remarks that "Dr. Fenwick of Montreal saws both femur and tibia in a curved line, so as to make them fit together more closely and accurately than they would do otherwise." The bones have been sawn in all kinds of ways[12]—obliquely by Billroth, in a kind of zigzag by Albert, and the exact reverse of that which I have described by Sédillot. However, none of these methods seem to be based upon the principle of attempting to retain the original fitting of the bones and the action of the ligaments.

The operation which has just been described has been done four times since 1889. A youth who was operated on in 1889 was earning his living three years afterwards and his father wrote: "He gets about freely and does not complain of it in any way; it is filling out very nicely and straight." Mr. Mark Taylor, writing about a youth operated upon in April, 1896, says that now "the leg is in very good position; no pain or tenderness anywhere." The photographs which Mr. Taylor sent certainly bear out the statement as to the position of the limb and also show that it is exceedingly well developed. In a third case done nearly a year ago the patient has a good and straight limb, but I doubt whether the union is yet bony. She had a septic sinus at the time of operation and the wound suppurated. The fourth case was, as I have already said, a comparative failure, because I did not thoroughly remove all the synovial membrane about the crucial ligaments and behind the condyles. This omission evidently needs to be particularly guarded against.

So far this operation seems to me to have the advantage of treating the bones so as to make it much easier to keep their cut surfaces in contact and at rest; no lateral movement or rotation is possible. Also, under favourable circumstances no falling backwards of the tibia can occur; next, the growth of the epiphyses is less interfered with; and, finally, the ultimate result is a very solid synostosis, with hardly any tendency to flexion. To gain these advantages the patient runs no risks beyond those of the usual operation.

Upper Berkeley-street, W.

A CASE OF ACTINOMYCOSIS TREATED BY IODIDE OF POTASSIUM.

BY COLVIN B. M. SMITH, M.B. DURH.

IN view of the facts that three cases of actinomycosis, treated by iodide of potassium at the Bristol Royal Infirmary, have been recently recorded[1] and that there has been some discussion as to the efficacy of the drug as a specific for this disease, the following note of a case may be of interest. A man, a farm-servant, aged twenty-seven years, consulted me on Dec. 7th, 1894, about a swelling in the cheek which caused him pain and prevented him from opening his jaw properly. He first noticed in October, during the harvest time (in Aberdeenshire) a small lump, "like the head of a pin," on the side of his neck, behind the lobe of the ear. This lump, he said, was moveable and could be pushed up and down under the skin with his finger. This increased in size

Hosted by Google

steadily, so at last he sought medical advice. His condition was as follows. There was a hard swelling under the zygoma, extending downwards for about an inch and outwards below the ear for about an inch. The skin over the tumour was slightly red, and there was pain on pressure. He was unable to open his mouth more than half an inch, and therefore it was almost impossible to ascertain the condition inside, but, so far as could be seen, there was neither carious tooth nor wound of any kind. He was recommended to stay at home, to apply poultices, and to take one drachm three times daily of the syrup of iodide of iron. During the next three days the swelling increased and became more painful, and on Dec. 10th the patient was almost unable to open his jaws. The syrup disagreed with his stomach and was discontinued, and iodide of potassium ointment was used externally. On the 11th the swelling, which appeared to be travelling downwards, showed signs of fluctuation, so an incision was made, but only a little blood came away and very slight relief was obtained. No improvement followed during the next few days, and the mouth could not be opened wide enough for the tongue to be protruded. On the 17th the abscess was opened below the lobe of the ear, and a good deal of pus was obtained, in which no granules were noticed. The inflammation descended along the course of the sterno-mastoid towards the clavicle; and on the 27th another incision was made below the angle of the jaw. The pain was now constant, and the jaws were closed. On Jan. 9th, 1895, the swelling had descended to the clavicle, leaving behind an indurated track of a purplish-red colour, with inflamed lymphatic vessels extending up the neck. An incision was made above the clavicle, and a copious flow of pus resulted, in which nothing special was noticed. It was not until three days later that I, while dressing the neck and syringing the sinus with boracic lotion, noticed, in a bad light, several yellow granules. On questioning the patient, he told me that several days previously, while changing the dressing, he had "squeezed the lump in his cheek with his fingers," to relieve itching, and that "scores of bright yellow little lumps dropped down on to the floor." During the next few days the patient was much better and several granules were obtained. On Jan. 20th, however, the inflammation had increased, there was a copious discharge of pus, and the last opening was surrounded by an intensely red erysipelatous area. The patient was ordered to take fifteen grains of iodide of potassium three times a day. After this date there was no further extension of the inflammation and on the 28th the discharge had ceased, though the sinus was still open, and the indurated track from the cheek to the clavicle was easily felt. After this the improvement was continuous and the dose of iodide of potassium was gradually decreased and finally stopped. On Feb. 7th the patient was quite well. The sinus was closed and the incisions were healed, and the induration along the track of the inflammation was the only mark of the disease. This gradually faded and there was no recurrence.

In the first two cases at the Bristol Royal Infirmary the exact period of incubation is given, and was in each case about fourteen days. In my case no date could be given for the actual inoculation, but in all probability it occurred during the harvest (which is late in Aberdeenshire), and the period of incubation may be calculated at about two or three weeks. Dr. W. B. Ransom mentioned [2] that in Germany 77 per cent. of cases of actinomycosis occurred between the months of August and January, and Dr. Septimus Gibbon noted the prevalence of the disease during damp seasons. The harvest of 1894 in Aberdeenshire was a particularly wet one. With regard to the treatment, the cure was either spontaneous or the result of the exhibition of iodide of potassium. If it was spontaneous it is at least curious that it should have occurred, after months of no improvement, coincidently with the exhibition of the iodide of potassium. The iodide of potassium ointment seemed to be useless—probably it was not absorbed. I may mention that the patient declined to permit any surgical treatment.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TWO CASES OF ŒDEMA OF THE LUNGS IN CHILDREN TREATED WITH STROPHANTHUS.

BY A. MACGREGOR, M.D. ABERD.,
ASSISTANT PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

THE sudden and unexpected development of œdema of the lungs in the first case, and the gravity of the symptoms and the rapid and satisfactory action of strophanthus in both cases, may invest with sufficient interest the following notes to merit a place among the clinical memoranda of THE LANCET.

CASE 1.—A boy, aged seven years, suffered from chronic pleurisy and peritonitis. During the first six weeks in which he was under my care the temperature oscillated between 98° and 102° F. Suddenly œdema of the lungs developed, there was distressing dyspnœa, the pulse-beats numbered from 156 to 172 per minute, and the temperature rose to 103 8°. He was given carbonate of ammonia and tincture of digitalis in mixture, with the result that the frequency of the pulse was slightly diminished, but the general condition was not only not improved, but much worse. On May 1st, lividity of the face was very marked and the orthopnœa was most distressing. The pulse-rate was 144, the respirations 70, and the temperature 102°. The mixture of carbonate of ammonia and digitalis was discontinued, and one minim of tincture of strophanthus given every four hours. On May 2nd the pulse-rate was 132, the respirations 54, and the temperature 101° in the morning and 99° in the evening. The dose was increased to two minims every four hours. On May 3rd the pulse was 120, and the respirations 44; the morning temperature was 99°, and the evening temperature 99 4°. On the 4th the pulse was 108, and the respirations 36; the morning temperature was 98°, and the evening temperature 98 5°. On the 5th the pulse was 110, and the respirations 30; the temperature was 97 8°. On the 6th the pulse was 108, and the respirations 26; the morning temperature was 97 6°, and the evening temperature 98·5°. On the 7th the pulse was 100, and the respirations 24; the temperature was 98 5°. The lungs had now almost completely cleared up, the lividity and dyspnœa disappeared, and from the very acute pulmonary œdema the patient rapidly recovered.

CASE 2.—A girl, aged nine years, was seen by me for the first time on Nov. 9th, three weeks after the onset of an attack of scarlet fever. The skin was desquamating, there was general anasarca, the face and lips were very livid, there was orthopnœa with incessant, short, distressing cough, the lungs were water-logged, and there was considerable effusion into the pericardium; the pulse-rate was 164, the respirations 74, and the temperature 102° F. No urine had been passed for some time. Two minims of tincture of strophanthus were given every three hours; brandy was also given, and jacket poultices were applied to the chest. On Nov. 11th urine amounting to about four ounces was passed for the first time, the bowels also acting at the same time. The patient was easier, the cough was now only occasional, and the œdema of the lungs was found to be passing away. The pulse was 128, the respirations were 52, and the temperature 101°. The dose of strophanthus was increased to three minims every three hours. On Nov. 12th the pulse was 60, respirations 30, and the temperature 99°. The strophanthus was reduced to two minims every six hours. On the 13th the pulse was 76, respirations 28, and temperature 99°. On the 14th the pulse was 64, respirations 22, and temperature 100°. The first specimen of urine obtained for examination was found to contain numerous blood corpuscles, and blood and epithelial casts. The quantity passed daily continued to increase. On Nov. 16th twenty-nine ounces were passed; the specific gravity was 1014, and there was only a trace of albumin. The pulse-rate was then 60, and the strophanthus was discontinued. The patient made a rapid and complete recovery.

ACUTE PEMPHIGUS (?), AND EPIDEMIC ACUTE ECZEMA.

BY DR. JÓN JÓNSSON (OF REYKJAVIK),
GOVERNMENT MEDICAL OFFICER IN ICELAND.

IN THE LANCET of Oct. 31st, 1896, an unusual lesion of the skin was described (on page 1212) by Dr. James Priestley, who further mentioned that he was in hopes of obtaining suggestions as to the diagnosis from those who had experience of similar cases. Dr. Priestley's patient presented numerous large bullæ over the greater part of the body, most of them on an erythematous base, and some on normal skin; there was high fever; and death occurred after the symptoms had continued for about five and a half days. Just a year ago I had a case in which the lesion of the skin was apparently very similar, although the illness followed a milder course. The patient was a man, fifty years of age, and came under my care on March 22nd, 1896, a week after the beginning of the eruption. The vesicles were at first small, but in a few days developed into large bullæ, which measured from an inch to an inch and a half in diameter and spread themselves over the whole surface of the body, being confluent in various places. Both scapular regions were totally denuded of epidermis, and presented a raw surface about 18 cm. (7¼ in.) long and 10 cm. (4 in.) wide. In the iliac and inguinal region there was a band encircling the body, from four to five inches wide, totally denuded of epidermis and ulcerated. It was quite impossible to find on the body a place as large as the palm of the hand free from bullæ except on the legs, ankles, and feet, the eruption being more scattered there than elsewhere. The edges were inflamed, but there was no infiltration of the skin except on the right knee, where I applied carbolic acid lotion, with the result that the growth of the vesicles was stopped and healing followed, with desquamation of the epidermis at the infiltrated place. On the first evening of my attendance the temperature was 39° C. (102·2° F.) and the pulse 100. During the ensuing eight or nine days the temperature varied between 38 5° and 41° C. (between 101 2° and 105·8° F.), the latter being the highest temperature which was noted; the pulse ranged between 100 and 130. The eruption was copious on the hairy scalp and there were several vesicles on the tongue, but there was no pharyngitis. I estimate that an area extending over more than two-fifths of the whole surface of the body was denuded of skin. After this date the fever rapidly diminished, repair of the skin commenced, and in from sixteen to eighteen days all the ulcers were healed. The patient was a healthy man of a full habit of body; he had passed through an attack of typhoid fever some time before. There was no other case associated with this one, and the cause of the illness was unexplained.

Dr. Paul of Nagasaki, Japan, writing in THE LANCET of Feb. 13th, 1897 (p. 437), referred to Dr. Priestley's article, and described a case observed by himself in 1894, in which an infant suffered from acute pemphigus and acute eczema of the face, the two diseases being intercurrent, but independent in course. In connexion with this subject I may add that in the years 1893–94 Iceland was visited by an epidemic of acute eczema of the face, or contagious impetigo, especially attacking young persons and children. Many of the infants affected with the eczema suffered also from severe dermatitis with large bullæ on all parts of the body except the head. These two diseases—the eczema on the face and the pemphigus on the body—were apparently distinct; most of these cases terminated fatally.

A CASE OF SUPERFŒTATION.

BY H. W. MILLS, M.R.C.S. ENG., L.R.C.P. LOND.

AS superfœtation is undoubtedly a very rare occurrence—the mere possibility has been denied by some authorities—it is advisable that all apparently genuine cases of this abnormality should be recorded.

On Sept. 2nd, 1896, I was called to a woman, aged forty-two years, who was reported to have had a miscarriage. She had only had one previous pregnancy, which resulted six months previously in a three months' abortion. On examination I found a piece of umbilical cord projecting through the external os; the internal os just admitted one finger. I removed piecemeal the placenta, which was firmly adherent. I then turned my attention to a vessel full of blood-clots passed before my arrival, and discovered a fœtus of about sixteen weeks old and also a perfectly fresh healthy ovum of about seven weeks. This case much resembles one recorded by Dr. Tyler Smith, quoted by Dr. Galabin,[1] and, as in that case, the woman had had periodical discharges of blood, three in number, though she cannot be certain whether or no they correspond in point of time with what would have been her ordinary menstrual periods. Such cases as these do not, of course, conclusively prove the possibility of superfœtation, for they are open to the explanation that the younger fœtus—though apparently quite fresh and healthy—may have been retained dead without decomposition for two months or so; but I think the evidence points rather to the former than to the latter explanation, and affords about as strong proof as we are likely to get under the circumstances. It is difficult to see what should have caused the death of the younger fœtus; there was no history of syphilis on either side; moreover, "the struggle for existence" cannot be so very severe at seven weeks. The uterus in this case was not double.

LONDON HOSPITAL.

CARCINOMA OF THE RECTUM; KRASKE'S OPERATION; RECOVERY; REMARKS.

(Under the care of Mr. FREDERIC EVE.)

THIS operation has not yet obtained that position in the estimation of the profession which its advantages entitle it to possess. The idea of cutting through the sacrum in order to get at the rectum appears to many as such a formidable procedure that they hesitate to recommend it in the early stage of disease when it can be carried out most satisfactorily, and perhaps only give it a trial when the patient himself demands it because his sufferings are becoming more than he can bear. Heidenhain considers that "the only local contra-indication to the operation is the extension of the growth to the prostate, bladder, or ureter."[2] There can be no doubt, however, that if the loose connective tissue about the rectum is involved the case is very unfavourable, as it also is if the retro-peritoneal glands are affected. Dr. Allison states that "the reported cases of excision of the rectum after Kraske's method for cancer show a mortality of 30 per cent., with a recurrence in 40 per cent. of the recoveries. This includes, however, many inoperable cases, as is proved by a mortality of 8 per cent in the hands of some surgeons in properly selected cases."[3] Senn writes "that the surgeon who removes the cancer of the rectum by excision will have a great mortality, while the one who follows the loose connective tissue spaces, resorts to blunt instruments, and carefully guards against hæmorrhage will show the best results."[4]

A man, aged fifty-one years, broken down and prematurely aged, was admitted to the London Hospital with advanced cancer of the rectum. The disease occupied the upper part of the bowel and could just be reached by the finger. The affected area was evidently adherent anteriorly, although not firmly. There was no evidence of enlargement of the liver. The patient's attention had first been drawn to the trouble by the passage of blood and watery discharge commencing two months previously. His condition was

explained to him and that it might be impossible to remove the whole of the disease; but he expressed an urgent wish that an attempt should be made, and it was therefore decided to perform Kraske's operation. On April 9th, 1896, a preliminary inguinal colotomy was done in the usual way. On May 12th (the patient's general condition having meanwhile improved) Kraske's operation was performed, Heinecke's incision being adopted. A vertical cut was made from the coccyx upwards over the middle of the sacrum; this was joined by a horizontal incision at the level of the third sacral foramina. The sacrum and coccyx were then divided with the saw in the middle line as high as the horizontal incision, and the lateral sacral wings severed with the chisel just below the level of the third foramina. The two osseous and cutaneous flaps were then turned aside and the rectum exposed. An attempt was made to separate the rectum from the bladder by dissection and with the finger, but failed on account of intimate adhesions. The lower part of the incision was therefore prolonged around the anus, and the separation of the bowel was commenced from below upwards. The carcinoma was found to extend above the level of the reflection of the peritoneum. This was divided, and after a sufficient extent of the mesorectum had been severed between ligatures the whole of the diseased portion of the bowel was readily brought down into the wound. Above the growth a ligature was passed around the bowel, which was divided below it. The surface to which the growth was adherent was thoroughly scraped and cauterised and the opening into the peritoneal cavity closed with sutures. The rectal stump was fixed to the skin at the upper part of the wound, the divided surface of the sacrum united by sutures passed through the periosteum, and the wound in the integuments closed. Subsequently the sutures attaching the rectal stump to the skin gave way and the stump became retracted, thus opening up the large cavity from which the bowel had been excised. This required packing with iodoform gauze, but the cutaneous incisions united by first intention. The patient is now doing his work, and is much improved in health. A slight fistula discharging mucus remains at the point where the stump of the bowel was attached to the integument.

Remarks by Mr. EVE.—The operation bears out all the advantages claimed for it by its advocates. There was very little loss of blood after the first incisions were made. The field of operation was fully exposed to view. An extensive and adherent mass of carcinoma occupying the first part of the rectum was apparently completely removed. The hollow of the sacrum could be thoroughly explored for infected glands. It can scarcely be doubted that the preliminary colotomy was a wise precaution in consideration of the seat and extent of the disease, and condition of the patient's health. The progress of the above case contrasts favourably with one reported by me in the Transactions of the Clinical Society of London for 1887. In this five inches of the rectum were removed through the ordinary anal incision, the reflection of the peritoneum being divided all round. This allowed the bowel to be very freely brought down. Some time afterwards the patient was admitted to the hospital in my absence with chronic obstruction, and died unrelieved. The post-mortem examination showed that the obstruction was due to adhesions of coils of small intestines to the cicatrix in the pelvis. This would not have occurred had it been possible to suture the opening in the peritoneum. It is noteworthy that there was no recurrence of the disease *in situ* and no secondary growths existed in the liver. I may say, in conclusion, that I would in future perform one or other of the modifications of Kraske's operation in place of the old operation, except for disease limited to the lowest portion or for circumscribed recent growths quite at the lower part of the middle portion of the rectum.

THE CENTRAL LONDON OPHTHALMIC HOSPITAL.—The annual meeting of the Central London Ophthalmic Hospital was held on Feb. 25th, Mr. J. Stamford Burrows presiding. The report showed that during 1896 there were 197 in-patients; there were also 10,520 out-patients, who made 26,200 attendances. The total income received for general purposes during 1896 was £1171, and the expenditure was £1174; the corresponding figures for 1895 were £887 and £929 respectively. Owing to the great increase in the number of the patients there was an urgent necessity for an enlargement of the buildings; a building fund had therefore been opened and £2046 had been received, but a further amount of £15,000 would have to be raised.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Clinical Bearing of some Experiments on Peritoneal Infections.—Removal of a large solid Tumour from the Retro-peritoneal Space.

A MEETING of this society was held on March 8th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Mr. HERBERT DURHAM read a paper on the Clinical Bearing of some Experiments on Peritoneal Infections. He referred first to the researches of Issaef, who had shown that a considerable degree of general resistance against pathogenic microbes was afforded by inducing leucocytosis. It was found that if sterilised water or broth or serum was injected into the peritoneal cavity on the preceding day the animal could take with impunity fifteen times the ordinary lethal dose of a culture of cholera vibrios The protective effect was much increased if serum from an animal immunised against the cholera vibrio was employed. Mr. Durham, experimenting on these lines, had succeeded in protecting guinea-pigs by sterile injections of nutrient broth against bacterium coli, bacillus pyocyaneus, bacillus prodigiosus, and bacillus typhosus. The protection was due to two factors—(1) increased bactericidal power of the peritoneal fluid after injection, and (2) the presence of a very large number of active phagocytes which are not seen in normal peritoneal fluid. Mr. Durham suggested that an attempt might be made to afford protection in man before operations through the peritoneum in such cases as perityphlitis, tubal abscess, and the like, in which there was some chance of pus getting into the peritoneal cavity. In the majority of cases the active organisms were streptococci, and he thought it would be advisable to protect the peritoneum with anti-streptococcic serum the day before proceeding to open the abdominal cavity. The bacterium coli appeared to be much less potent in the production of peritonitis than was often taught. Mr. Durham pointed out that there might be no lymph and no organisms present in the peritoneal fluid in cases which died rapidly, but that in the lymph spaces of the omentum and other peritoneal membranes abundant organisms could be demonstrated. The injection of anti-streptococcic serum would not only increase the general resistance of the tissues, but would afford specific immunity against streptococcal invasion. Mr. Durham then drew attention to the treatment of general suppurative peritonitis and insisted on the importance of thoroughly cleansing the omentum and the space between the liver and the diaphragm, as microscopic examination showed that it was there that organisms were most thickly aggregated.—Mr. C. B. LOCKWOOD agreed that all the ordinary naked signs of peritonitis might be absent at the necropsy, and yet examination microscopically would reveal masses of organisms in the lymphatics. There was undoubtedly a great difference in the course of the disease according to the organisms present, and the streptococcal forms were much more virulent than those due to the bacterium coli. Owing to the multiplication of the microbes in the substance of the membranes, and not on their surface, it was practically impossible to dislodge them, and if Mr. Durham's plan of preparing the tissues to resist their entrance proved to be efficacious it would be a very valuable expedient.—Mr. HARRISON CRIPPS said that it was curious that in those cases where fœtid pus escaped into the peritoneum during an operation the more severe forms of peritonitis were very rare. Possibly the previous existence of the pus in close contact with the peritoneum had some protecting effect. He did not see how the washing out of the space between the liver and the diaphragm was to be carried out, as it was so high and the surfaces were in such very close apposition.

Mr. MARMADUKE SHEILD read a paper on the Removal of a large solid Tumour from the Retro-peritoneal Space. The patient was a woman, fifty-two years of age, who was the subject of complete uterine prolapse. There was a large abdominal tumour passing up from the pelvis almost to the ensiform cartilage. It was soft, elastic, and semi-fluctuating, and was believed to be ovarian. When laparotomy was performed there were many laminæ of condensed fibrous tissue in front of the tumour which had to be stripped off the tumour, which was found to be lying in front of the spine,

Hosted by Google

but was readily separated from the aorta and vena cava. The tumour was definitely encapsuled, but was firmly adherent to the bladder. Owing to the rapidity with which the operation had to be performed the exact relations of the tumour could not be accurately made out. There was an extraordinary number of adventitious adhesions containing large vessels. The tumour proved to a fibro-myoma when examined by Dr. Rolleston. The exact origin of the tumour was not easy to determine. It might be a sub-peritoneal fibroid which had become detached from the uterus and formed new attachments or it might have grown from the unstriped muscle found in the broad ligament and the root of the mesentery, Most of the recorded cases had been fibro-lipomata, so soft as to give rise to a diagnosis of ascites. Sarcomata also occurred. The diagnosis was usually one of extreme difficulty. Often the intestines became so flattened by pressure that it was not possible to obtain resonance over the colon which lay in front of the tumour.—Mr. F. S. EVE thought that the tumour originated in the unstriped muscular tissue which was found at the root of the mesentery. He had examined a tumour removed from this situation by Sir Spencer Wells, which proved to be a fibro-lipoma.—Mr. LOCKWOOD remarked that sarcomata in this position were usually encapsuled and showed little tendency to infiltrate locally, and that their removal was easy unless they were very soft. He thought that an important point in diagnosis was the occurrence of varying areas of resonance over the colon.—Mr. HARRISON CRIPPS agreed that there was very little tendency for retro-peritoneal tumours to infiltrate and they were less apt to recur than those in other parts. He thought that many of them grew from the broad ligament and were not, strictly speaking, retro-peritoneal. He thought that probably in this case the tumour was originally a detached uterine fibroid. In operating on such cases the surgeon was often embarrassed by the number of adhesions that he had to cut through, so that he did not know whether he had got down to the peritoneum. In those circumstances it was best to follow Sir Spencer Wells's plan and extend the incision upward, and to get into the peritoneal cavity higher up; it would then be easy to get one's bearings.

MEDICAL SOCIETY OF LONDON.

Excision of Knee.—Intestinal Neurosis.

A MEETING of this society was held on March 8th, the President, Mr. REGINALD HARRISON, being in the chair.

Mr. C. B. LOCKWOOD read a paper in which he reviewed the operations for Excision of the Knee and described a new procedure—Osteoplastic Excision. The paper will be found printed in full on page 732 of this issue.—Mr. MARMADUKE SHEILD thought the operation would prove to be a good one, as it appeared satisfactorily to resist the tendency to lateral displacement of the knee which often caused the surgeon to be disappointed with the result of his operation. Such displacement might occur even twelve months after the operation, and was most liable to occur among hospital patients, who could not carry out the prolonged rest which was essential, and the operation, therefore, would be especially useful for such patients. Complete fixation was an absolute necessity, and he thought that Howes' splint, which allowed the dressings to be changed without removal of the splint, answered all purposes. In performing Mr. Lockwood's operation great care would have to be taken that no disease was left behind in the condyles or in the patella.—Mr. STANLEY BOYD said that in young subjects he had performed arthrectomy in preference to excision because injury to the epiphysis was thus avoided. In Mr. Lockwood's operation the whole of the epiphysis was not removed, and it would be interesting to observe whether the portion of the epiphysis left would be sufficient for growth. He did not think there was much advantage in retaining the action of the quadriceps: complete fixation was best. He preferred Thomas's splint to the limb being fixed in position with sterilised bandages before the dressing was applied. He was accustomed to fix the bones by two two and-a-half inch carpenter's screws. There was no satisfactory explanation why bony union was so difficult to obtain. He suggested that it was owing to the injury being almost confined to the bone, the periosteum being hardly implicated.—Mr. G. R. TURNER pointed out that Senn had found a method based on the same principles successful in obtaining union in ununited fracture.—Mr. LOCKWOOD, in reply, said that it was useful to preserve the quadriceps, because it prevented the flexion which was otherwise apt to occur. He thought that Howes' splint was admirable for many purposes, but he did not think that any splint was effectual in keeping the surfaces in perfect apposition unless the hip-joint was also controlled, and he considered that a splint should reach up to the axilla and prevent the patient sitting up in bed.

Mr. CLINTON DENT read a paper on some cases of Intestinal Neurosis, especially with regard to the question of surgical interference. The first case was that of a man, thirty-five years of age, who had suffered from symptoms attributed to internal stricture of the small intestine, extreme wasting, and severe epigastric pain occurring at a regular interval after food. When he was placed under an anæsthetic a swelling the size of a sausage could be felt above the umbilicus. An exploratory incision was made, but nothing was found. All the symptoms disappeared and the patient completely recovered. The second case was that of a young man, twenty-seven years of age, who commenced with symptoms pointing to renal calculus. The kidney was explored; nothing was found, but the renal symptoms disappeared. A few weeks later, however, he was seized with attacks in which he had headache and pains in the thighs; his temperature rose to 103° F., he had rigors with profuse sweating, and frequent vomiting. A swelling like a thick cord could be felt occasionally in the right iliac fossa. On opening the abdomen the only structural alteration that could be made out was a small adhesion between the cæcum and omentum. But either from the manipulations or exposure to the air the first few inches of the colon were seen to contract into a rounded mass, which had no doubt been the cause of the intermittent swelling felt in the iliac region. Only temporary relief was given to the symptoms by breaking down the adhesions. Afterwards relief was afforded by washing out his stomach, but at the present time symptoms had returned and closely simulated biliary colic. The third case was that of a man, fifty years of age, who had attacks in which he was seized with pain in the right ischium, which quickly radiated over the whole abdomen. This was followed by copious eructations and often by vomiting. There was no evidence of organic disease, and all the symptoms were relieved by abdominal massage. In many cases these symptoms were associated with some lesion which by itself would be insufficient to cause them, as in the case of a man, admitted for syphilitic brain disease, who was suddenly seized with abdominal pain, &c. The stomach was found on operation to be bound down by adhesions. These were freed, but as the symptoms persisted pyloroplasty was performed. The relief, however, was only temporary, and he still has very frequent vomiting, which appears to have very little effect on his general health. Purely functional cases showed a great tendency to relapse, and he thought that laparotomy, unless there was clear evidence of organic trouble, was inadvisable.—Mr. MARMADUKE SHEILD thought that the recovery from symptoms of renal calculus by operation when no stone was found was due to the squeezing of the kidney during the operation. The cases described by Mr. Dent were very puzzling, as it was difficult to know how much weight to attach to the symptoms. Sometimes hysterical manifestations might make one overlook evidence of organic disease. He quoted the case of a young woman who was admitted to St. George's Hospital suffering from pain, wasting, and almost constant vomiting, which was at first believed to be neurotic. On exploring the abdomen, however, the peritoneum was found studded with tubercles, and there was a band which bound down the jejunum. When this was relieved the symptoms disappeared and complete recovery followed.—Mr. LOCKWOOD thought that there was often some actual disease present. In one case in which he explored for calculi in the gall-bladder and found everything apparently normal, he thought now that there might have been some duodenal ulceration.—The PRESIDENT referred to the extensive train of nervous symptoms which are sometimes associated with a varicocele of inconsiderable size, which could not be directly due to the physical conditions present.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on March 4th, the President, Dr. R. H. MILSON, being in the chair.

Dr. G. A. SUTHERLAND showed a girl eleven years of

Hosted by Google

age suffering from Tachycardia and Cyclic Albuminuria. There were other disturbances present in connexion with the heart and the kidneys, but he considered that they were functional rather than organic in origin.—The PRESIDENT stated that he had a patient whose pulse had averaged from 128 to 130 beats in the minute, and frequently reached 140, for the last ten years. Although he had seen many physicians, the cause of the quickness had never been determined.—Dr. COCK mentioned a case of a healthy woman, aged thirty-six years, whose pulse was normally 100, and that this quickness had persisted after an attack of puerperal septicæmia from which she suffered ten years ago.

Mr. JACKSON CLARKE showed a child, aged five years, who had a Marked Lateral Deviation of the Spine to the Left in the Dorsal Region. There was a slight deformity present at birth, and this had become worse during the first two years of life owing, he believed, to the child having suffered from rickets. At the end of this time the case came into the hands of Mr. John Poland, who had applied the splint (Chance's), which Mr. Clarke demonstrated. No further deviation had occurred since the splint had been worn. The importance of recognising and treating rickety curvature of the spine, whether it took the more usual form of a single posterior incurvation or the less common lateral deviation, was emphasised.—Mr. NOBLE SMITH remarked that the case of lateral curvature shown by Mr. Jackson Clarke was probably due to rachitic softening of the vertebræ, but such cases were rare. The pathology of lateral curvature had not yet been satisfactorily described. He could not adopt the view that weakness of muscles alone was the usual or at all a common cause. Only 1 or 2 per cent. of the cases which he had seen were clearly rachitic, and the softening and relaxation he referred to were due to some other pathological condition or to excessive rapidity of growth. Sometimes lateral curvature occurred in young people whose muscles were well developed, and he showed photographs of such cases in youths whose muscles were obviously strong. He also showed photographs of cases of lateral curvature in which a condition of osteoporosis existed. In discussing the treatment Mr. Noble Smith urged that the popular treatment by exercises alone was only suited to those few cases which were hysterical or very slight, and that for the very large number of patients who suffered from real lateral curvature mechanical help was necessary, and if judiciously applied was always successful. The splint which Mr. Jackson Clarke had shown, and which was used at the City Orthopædic Hospital, was very efficient. It was constructed upon quite different principles from those devised by instrument makers. These principles of construction demanded not only mechanical knowledge, but also the whole knowledge of the surgeon. By the use of this apparatus the muscles were encouraged to act, instead of being interfered with; the chest was developed, not depressed; and the shoulders were drawn backwards, not pressed up by crutches. In very weak patients the strength of the spine was insufficient at first to tolerate special exercises; but by means of this support the ordinary exercises of play and movement were freely permitted, while the spine was prevented from falling into wrong positions. The result was that when the patient had been made straight and subsequently had grown strong the apparatus could be thrown aside without fear of a relapse. In some cases exercises in addition to the mechanical support were of great benefit, and massage and hand pressure were also valuable remedies.

Mr. E. W. ROUGHTON showed: 1. A case of Sacro-iliac Disease which had been completely cured by scraping out the joint. The chief symptom of disease in the case was a cold abscess which formed over the dorsal aspect of the joint, and when the latter was opened it was found to be completely disorganised. 2. A case of Congenital Deformity of both Hands in a woman. The three central digits were shortened. A skiagram showed that the shortening lay in the metacarpals and not in the phalanges.[1]

Mr. SEFTON SEWILL showed a young woman in whom he had treated an Empyema of the Antrum by making an opening through the alveolus of a molar or bicuspid tooth and exhibited the instruments he employed. In cases where he removed a tooth immediately before operation he found the three sizes of trocars shown all that was necessary to perforate. In edentulous cases spear-headed drills driven by the dental engine were a great assistance, indeed, almost indispensable. He next described the drainage apparatus, consisting of a gold tube of as large calibre as possible, its lower orifice being closed by a split pin during mastication. This tube fixed to a gold plate held *in situ* by bands round adjacent teeth provided efficient drainage, and had this advantage, that a patient could syringe out the antrum without removing the plate and tube.—Dr. PEGLER, Dr. HILL, Dr. SCANES SPICER, and others discussed the case.

[1] We have received these skiagrams from Mr. Roughton, and hope to publish them shortly.

OBSTETRICAL SOCIETY OF LONDON.

Exhibition of Specimens.—President's Inaugural Address.—Cyclical or Wave Theory of Menstruation.

A MEETING of this society was held on March 3rd, Dr. C. J. CULLINGWORTH, President, being in the chair.

A letter of condolence on the death of Sir Spencer Wells from the Berlin Obstetrical and Gynæcological Society was read.

Mr. W. DUNCAN showed five Fibromyomata removed by abdominal section.

Mr. A. F. STABB showed a Uterus with Interstitial Fibroid removed by abdominal hysterectomy in a young woman aged twenty-six years.—The PRESIDENT and Mr. ALBAN DORAN made remarks.

Dr. CULLINGWORTH then gave his Inaugural Address on the Undiminished Mortality from Puerperal Fever in England and Wales, which was published in full in THE LANCET of March 6th.

Dr. W. S. PLAYFAIR moved a cordial vote of thanks to the President for his most interesting and instructive address, and said he could conceive no topic more useful or one more likely to have a beneficial effect.—This was seconded by Dr. CHAMPNEYS and carried unanimously.

Dr. ARTHUR E. GILES read a paper on the Cyclical or Wave Theory of Menstruation, based on observations on the temperature and the pulse before, during, and after menstruation. The temperature observations embraced fifty menstrual periods in forty-five patients; from the fifty cases a composite curve had been drawn up, which might be regarded as the type of the temperature curve in relation to menstruation. It showed that the temperature was lowest at the middle of the inter-menstrual period; it gradually rose, attaining its maximum two days before menstruation. There was a sudden drop on the day preceding the flow, with a second slighter drop at the end of the period. It rose slightly for the first week after the cessation of menstruation, and there was a third fall at the beginning of the inter-menstrual period. The observations of Jacobi and Reinl had been similarly employed in the construction of composite curves; these present features similar to those shown by Dr. Giles's curve. As regarded the pulse, sphygmographic tracings had been obtained from seven patients, covering nine menstrual periods and forty observations. They show that the blood pressure was greatest on the first two days of menstruation and on the day preceding; it was lower during the remainder of the period, rising again slightly after its cessation. The total variation, both in temperature and pulse, was comparatively limited. Dr. Giles then discussed the bearing of these facts on the cyclical theory of menstruation, and concluded that this theory as ordinarily stated was insufficient as an explanation of the origin of menstruation. But, taken in a modified form, the cyclical or periodic theory might be accepted as giving a connected idea of the meaning of menstruation, which might be regarded as the conclusion of the reproductive phase of an alternation of nutritive and reproductive activity or, in other words, as a repeated preparation for the reception and nutrition of a fertilised ovum. In the absence of such an ovum menstruation occurred as a "missed pregnancy."

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

An Apparatus for Preventing Talking during Sleep.—Copper Amalgam as a Filling Material.—The Discolouration of Copper Amalgam.

AN ordinary meeting of this society was held at 40, Leicester-square on March 1st, Mr. J. FAIRBANK (Vice-President) being in the chair. The minutes of the previous meeting were read and confirmed.

Hosted by Google

Mr. ROBBINS mentioned the case of a patient who applied to him for an apparatus which would interfere with his articulation and so prevent him talking in his sleep, for being a Government official and having to live in a bungalow where the partitions between the sleeping rooms were very thin he was afraid he might divulge some official secrets. Mr. Robbins explained and exhibited the appliance he had made, and stated that the result produced was most satisfactory.

Mr. J. H. BADCOCK read a paper on Copper Amalgam as a Filling Material, its merits and demerits. He remarked that it possessed the advantage of working smoothly and adapting itself perfectly to every part of the cavity, the shrinkage so common with most amalgams being in all probability entirely absent. Its supposed power of arresting caries by virtue of its antiseptic action was of no practical utility, and should be absolutely disregarded as being without clinical significance. Referring to the disadvantages of copper amalgam, he thought the most important was its tendency to "waste," more especially near the gum margin, with the result that caries recurs, and is frequently not discovered until the pulp of the tooth is exposed. The great tendency to discolouration was also an important disadvantage, and for this reason he considered that it should never be used in any tooth when staining would be objectionable. The opinions of various writers, both in this country and America, were quoted, Mr. Badcock giving a most concise and complete *résumé* of the whole question.

Mr. KENNETH GOADBY read a paper on the Discolouration of Copper Amalgam. He first dwelt upon the supposed antiseptic properties of copper amalgam and enumerated researches he had undertaken in this connexion. Plates of agar and gelatin were inoculated and small pellets of amalgam dropped on them. In the gelatin plates, three in number, a development of bacteria took place right up to the filling, and practically the same condition was seen in the agar plates. A series of tubes of broth, saliva, and gelatin were also inoculated with cultures (1) from the mouth direct; (2) with streptococcus brevis; and (3) with impure cultures from the mouth. In all cases development of bacteria took place. His results, therefore, seemed to point to the fact that copper amalgam has practically no antiseptic action. With regard to the black discolouration of copper amalgam Mr. Goadby stated that it was due to the formation of copper sulphide, and recounted the following experiments he had made in connexion with this point. Several tubes of saliva were taken and small pellets of amalgam dropped in; a solution of sulphuretted hydrogen was next added and the tubes placed in a chamber at the body temperature, within a short space of time the familiar sooty appearance was to be seen. Upon gently rubbing the black deposit a shiny surface was exposed, due no doubt to the mercury set free, and on again placing the amalgam in the solution the black sooty layer appeared. The "green" stain seen in connexion with copper amalgam was also referred to, Mr. Goadby recounting several experiments he had made with the object of discovering the actual cause of the colouration, and stated that as the result of his investigations he had no reason to suppose that the staining was due to copper sulphate as supposed by some. It, however, seemed probable that it was due to a salt of the nature of an amide.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

The Housing of the Insane and the Size of Asylums.—Exhibition of Cases.

A GENERAL meeting of this association was held at the Borough Asylum, Mapperley-hill, Nottingham, on Feb. 18th, under the presidency of Dr. JULIUS MICKLE.

Dr. RAYNER opened a discussion on the Housing of the Insane and the Size of Asylums. He drew attention to the fact that the number of patients housed in county and borough asylums in England and Wales had increased from 15,844 in 1859 to 63,957 in 1896, the increase since 1892 having been 8448, an average of more than 2000 per annum. He thought it was desirable, in the interests of the insane and of the community, to consider whether some improvement might not be made in the plan which now obtains of aggregating vast numbers in one building, by adopting plans of segregation in the degrees in which they may be useful and practicable. He divided the insane into the following groups: (1) the acute or hospital class; (2) the asylum class; (3) the employed or employable class; and (4) the helpless or workhouse class, with a terminal group—the infirmary dement. He considered success in treatment to be evidenced not only by the percentage of recoveries, but by the proportion of those who have improved so far as to be trusted with a great share of liberty. He considered skilled individual attention to be the basis of treatment, but that no amount of experience and skill will enable a physician to give the requisite attention to more than a certain number of cases, the amount of attention required varying greatly with the different groups. Individuality of responsibility is the corollary of individuality of attention, and should be delegated largely to assistant or deputy physicians. He considered that what was needed for London was not a lunatic hospital, but receiving houses or infirmaries, or even special wards in connexion with general hospitals, in which cases not yet certified or certifiable could be received for treatment, and from which, if necessary, they could be sent to the asylum. He considered that with adequate preventive treatment in the stage preceding the certifiable condition a certain proportion of cases might be saved from becoming bad enough for asylum treatment. He advocated also the further development of the colony system and of "boarding out" in suitable cases as a means of relieving our growing institutionalism. He concluded: (1) that the defect in the provision of treatment in the earliest stages of mental disorder was utter and complete; (2) that the defect in dealing with the improved or occupation class was very great indeed; (3) that the helpless workhouse class were massed in too great numbers and were too much isolated from their friends; (4) that the responsibility for treatment was not sufficiently and clearly delegated when the insane were treated in large masses; and (5) that the number of medical attendants was too limited. He considered that an establishment under one director should be made up as follows: a male and female side, each having a hospital for 200 beds, an asylum of from 300 to 400 beds, with farm or occupation colonies for 500 or more distributed over an estate of 1000 acres or more and with annexes for the helpless imbeciles and terminal dements, supplemented by a special organisation for developing "boarding out" in town or country. Each of these divisions should be under a physician absolutely responsible for the treatment of the patients under his charge, aided by junior assistants, but supervised by the physician-director. The line of advance in the treatment of the insane at present should be summarised as a need for "more brains and fewer bricks."

A discussion ensued in which the PRESIDENT, Dr. E. WHITE, Dr. THOMSON, Dr. SPENCE, Dr. MCPHAIL, Mr. HAYES NEWINGTON, Dr. MERCIER, Dr. CLAPHAM, Mr. ALEXANDER, Mr. EVAN POWELL, Dr. KAY, and Dr. T. W. MCDOWALL took part.

Dr. VINCENT and Dr. MONTGOMERY showed cases of interest from the wards of Mapperley-hill Asylum.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on March 5th, Mr. W. BRUCE CLARKE, the President, being in the chair.

Dr. CLIPPINGDALE showed a boy, aged ten years, who suffered from Congenital Ichthyosis. The areas of skin free from the disease were the front of each elbow, the back of each knee, and the face and neck.

Dr. C. W. CHAPMAN showed a man, aged forty-one years, with Aneurysm of the Thoracic Aorta.

Dr. H. P. POTTER showed a man, aged fifty-six years, with a Sarcoma of the Upper Jaw. The growth had been observed for about nine months. It measured five inches from side to side and four and three-quarter inches from above downwards. The sub-maxillary glands were slightly enlarged.

Mr. MCADAM ECCLES showed a man, aged fifty-two years, who had had his left Superior Maxilla removed for Sarcoma. The glands at the angle of the jaw were removed at the same time. The patient made a good recovery after the operation.

Hosted by Google

Mr. SWINFORD EDWARDS showed a man, aged fifty years, with Papillomatous Dermatitis around the Anus. The disease had lasted for four months. There were no signs of syphilis in other parts of his body. The anus was entirely surrounded by papillæ.

Dr. SEYMOUR TAYLOR showed:—1. A boy, aged fourteen years, with Hydrocephalus. The head began to enlarge at the age of seven months, continuing until the tenth year. The left side was more enlarged than the right. He had signs of a descending lesion affecting the crossed pyramidal tract on either side of the spinal cord. He was fairly intellectual. He had a lateral spinal curvature. 2. A boy, aged eight years, with Congenital Spastic Paraplegia. His parents were healthy. There was no history of forceps delivery. He had rigidity of both the upper and lower extremities, especially the latter. There were also flexion and adduction with increase of deep reflexes.—Remarks were made by Dr. W. S. COLMAN, Mr. MCADAM ECCLES, and Dr. SHUTTLEWORTH.

Mr. KEETLEY showed (1) a case of Congenital Dislocation of the Hip-joint after operation, and (2) a man from whom he had removed a Mammary Sarcoma.

Mr. L. A. BIDWELL showed a man, aged forty-six years, from whom he had removed an Epitheliomatous Tumour of the Abdominal Wall. The patient first noticed a pimple on the abdomen twelve months ago, which had gradually increased in size.

Mr. SWINFORD EDWARDS showed a man, aged thirty-two years, from whom he had removed a Renal Calculus.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Different Varieties of Aortic Regurgitation.—Exhibition of Cases.

A MEETING of this society was held on March 3rd, Dr. W. B. RANSOM, the President, being in the chair.

Dr. HANDFORD read a paper upon the Different Varieties of Aortic Regurgitation, and emphasised particularly the essential difference between those in which the lesion was stationary and those in which it was progressive, as well as the difference between the rheumatic and the atheromatous cases. The chief characteristics of the rheumatic cases were: (1) the disease came on at a much earlier period of life than atheroma, and was the main cause of aortic regurgitation arising between the ages of five and thirty-five years; (2) the arteries were generally sound; (3) the heart muscle was comparatively sound; and (4) apart from fresh attacks the valvular disease soon ceased to be progressive. In all these respects rheumatic aortic regurgitation differed essentially from the atheromatous, and the prognosis was very much more favourable. Not infrequently free regurgitation might exist for years with a complete absence of symptoms, even though the patient led an active life. The atheromatous cases were by far the most numerous and serious, and presented the following distinctions: (1) the disease was essentially a degeneration and arose in middle life, rarely before the age of thirty-five years, except where syphilis was the main cause; (2) the arteries were always involved to a considerable extent; (3) the heart muscle was rarely sound; (4) the disease was almost always progressive; and (5) it affected the male much more frequently than the female. Of the atheromatous cases there were four chief sub divisions, according to the mode of production: (1) the syphilitic, arising generally between the ages of thirty and fifty years, affecting sometimes mainly the aorta and branches, and sometimes mainly the valves, difficult to distinguish from fusiform aneurysm, and rapidly progressive; (2) those arising from laborious work in strong, muscular men, generally between the ages of forty and fifty years; (3) the arterio-sclerotic, arising between the ages of fifty and sixty-five years in the gouty and in men who habitually ate and drank too much, especially when combined with hard mental work; and (4) cases arising from "old age," about seventy years. No general rule could be laid down for all cases as regarded the use of digitalis. It was most useful where there was consecutive mitral disease with dropsy, next in the rheumatic cases and those arising from laborious work; the latter could often be enabled to continue their work by daily doses of digitalis. The chief cause of failure of compensation was degeneration of the ventricle from fibroid change, the prognosis of which depended mainly upon the degree of occlusion of the coronary arteries. When the fibroid change was advanced digitalis had little tonic stimulating effect upon the heart, and not only failed to do good, but did positive harm, because it still caused tonic contraction of the small arteries and increased the work of the failing heart. Digitalis was of great use in failure of compensation from temporary causes. It generally did harm in the syphilitic, the arterio-sclerotic, and the aged cases.—The PRESIDENT alluded to the group of cases occurring in young athletes which depended on over-exertion. He agreed that the condition of the cardiac muscle was the most important guide in the use of digitalis.—Dr. CATTLE remarked on the clinical difficulty of deciding whether a heart was "fatty."

Mr. A. R. ANDERSON showed a man on whom he had successfully operated nine months previously for Actinomycosis originating in the Vermiform Appendix and honeycombing the whole thickness of the greater portion of the anterior abdominal wall.

Dr. C. BELL TAYLOR showed: (1) a case of Double Iridectomy from one blow without injury to the vision; (2) Cataract in a patient aged seventy years dispersed by Electricity; and (3) Cyclitis followed by Atrophy of both Globes, with Secondary Cataract and Synechiæ, in which good vision had been restored by operation.

MANCHESTER MEDICAL SOCIETY.

Exhibition of Specimens and Skiagrams.—Subphrenic Abscess.—Detection of Sugar in the Urine.

A MEETING of this society was held on March 3rd, Dr. GRAHAM STEELL, President, being in the chair.

Dr. MORITZ showed the Larynx and Trachea and related the further history of a patient whom he had shown to that society in March, 1895.[1] The patient was then suffering from an agglutination of the vocal cords the consequence of syphilis, and had been tracheotomised. Inter-laryngeal operations proved only of temporary benefit, and the patient refused to undergo any further operative interference. In October, 1895, she again began to suffer from urgent dyspnœa, which was found to be due to stenosis of the trachea. This was gradually and efficiently dilated by means of Schroetter's catheters introduced through the tracheal opening. The patient did not show herself from April until September, 1896, when she again became dyspnœic. But now Schroetter's catheters of even a larger size (No. 4 or 5) could be passed without meeting with any apparent obstruction and gave no relief. It was therefore concluded that there was another stricture lower down. The patient died in October, 1896, from suffocation. She was seen shortly before her death, and though the inspirations were accompanied by some stridor the dyspnœa was most expiratory, and at each expiration a peculiar click-like sound, as that of the closing of a valve, was heard. At the post-mortem examination the larynx was found entirely occluded by cicatricial tissue down to the lower edge of the cricoid cartilage. The mucous membrane of the trachea was free from cicatrices. The lumen of the trachea showed a slight constriction at its lower part, whilst above this there was a fusiform dilatation in which the rest of the trachea was involved. At the constricted part the tracheal cartilages were extensively softened, and to this condition the dyspnœa and click-like sound were due. There was, further, a stenosis of the right larger bronchus just before its bifurcation. The right lung was emphysematous and the left lung normal. Dr. Moritz also made some observations on the comparative facility of inspecting the trachea through a tracheotomy opening by means of aural or nasal specula (Zaufal's), with the head of the patient extended well backwards

Dr. MCNAUGHT related a case of Subphrenic Abscess, probably due to rupture of the stomach and complicated by empyema, successfully treated by incision and drainage, and subsequent incision and resection of rib.

Mr. G. A. WRIGHT showed (with lantern slides) a collection of Skiagrams illustrating the Uses of the Process in General Surgery.

Dr. R. T. WILLIAMSON referred to the Difficulty of Detecting with certainty Small Quantities of Sugar in the Urine.

[1] THE LANCET, March 16th, 1895, p. 720.

Hosted by Google

Every test had some weak point, but by the following combination of tests a definite conclusion could be easily arrived at:—1. Apply Fehling's test. If no oxide of copper be reduced, or if there be a good reduction and other indications of diabetes be present, no further test is required. 2. In some cases other indications of diabetes are absent or the reduction of copper is slight. In such cases try the phenyl-hydrazin test — simplified method (test tube filled for half an inch with powdered sodium acetate, for half an inch with phenyl-hydrazin-hydrochlorate in powder, and the tube half filled with urine; keep boiling over a lamp for two minutes). A negative result shows that the substance reducing Fehling's solution is not sugar, and no further test is required. A positive result (deposit which under the microscope consists of yellow needle-shaped crystals in sheaves) indicates glucose; if scanty, possibly glycuronic acid. Lactose yields small yellow globules with very short spines. 3. Try the fermentation test (for twenty-four hours), using two tubes, one containing the suspected urine and the other normal urine for control (yeast = $\frac{1}{10}$ by volume). Excess of gas in the former tube indicates glucose. A negative result shows glucose to be absent or less than 0·1 per cent. 4. If the results be negative at the end of twenty-four hours, apply Fehling's test to the mixed urine and yeast. If Fehling's solution is no longer reduced, glucose which has been destroyed by the action of yeast is indicated. If Fehling's solution be still reduced, the reducing substance is not glucose.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Specimens.—Smegma Bacillus.

A MEETING of the Pathological and Microscopical Section was held on March 4th, Mr. F. T. PAUL being in the chair.

The following specimens were exhibited:—

Mr. T. H. BICKERTON: Intra-ocular Tumours mounted in glycerine jelly.

Dr. BUCHANAN: Specimens and drawings of Tuberculous Tumour of the Iris removed by Mr. Bickerton. The patient, a negro, aged four years, in June, 1893, had a small speck in the iris, which increased rapidly, the eye being enucleated in October. Twelve months later symptoms of cerebral tuberculosis set in and the boy died. The sections exhibited bacilli, giant cells, and early tubercle in the iris and choroid.

Mr. G. NEWBOLT: (1) A Villous Tumour of the Bladder which had been passed by the patient; and (2) Vermiform Process removed from a femoral hernia in a woman on account of strangulation.

Dr. LESLIE ROBERTS: (1) Parasitic Flora of Skin, cultures and sections under the microscope; and (2) Psoriasis, Lichen Planus, and Morphœa.

Mr. THELWALL THOMAS: A Dissection of the Neck in a case where all the carotid arteries and jugular veins had been divided with many nerves in the left side of the neck in a man whose case was recorded in 1895.[1] He lived for only two years, and died from lung mischief on the right side. From the root of the neck to the base of the skull on the left side only one small part of the external carotid artery could be found giving off the lingual and superior thyroid arteries; the stumps of the common carotid and internal jugular veins were merged in a cicatricial mass, which also involved the cut sympathetic and pneumogastric nerves. The circle of Willis was normal, the only apparent attempt at collateral circulation being a large vertebral artery on the left side, the deep cervical artery being smaller than that on the right side.

Mr F. C LARKIN: (1) Acute Necrosis of the Os Calcis. (2) Appendix Cæci removed from a Strangulated Hernia in which the cæcum and appendix were found in a child; and (3) Hypertrophic Prostate.

Dr. A. W CAMPBELL: (1) Tuberculous Growths in the White Matter of the Spinal Cord Posterior Columns; and (2) Tumour of the Posterior Nerve Root in the Sacral Region and Heterotopia Spinalis.

Dr. J. WIGLESWORTH: Cerebral Asymmetry.

Mr. PAUL, Mr LARKIN, Professor BOYCE, Dr. BUCHANAN, and Dr CAMPBELL joined in the discussions.

Dr GRÜNBAUM read a note on the Smegma Bacillus, and mentioned that he had succeeded in growing the organism in milk.

Mr. PAUL, Professor BOYCE, and Dr. N. E. ROBERTS joined in the discussion.

[1] Brit. Med. Jour., Dec. 7th, 1895.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases, Specimen, and Photographs.—A Case of Tetanus.

A MEETING of this society was held on Feb. 25th, the President, Mr. RECKLESS, being in the chair.

The following cases, specimen, and photographs were exhibited:—

Mr. HARRY LOCKWOOD: A case of Myositis Ossificans (previously shown) to demonstrate the progress of the disease.

Mr. HARVEY: (1) An adult with Facial Hemiatrophy; and (2) a child with Marked Congenital Asymmetry of the Head and Limbs.

Mr. ARCHIBALD YOUNG: A case of Intra-thoracic Growth.

Dr. WEARNE CLARKE (Chesterfield): Photographs of a case of Raynaud's Disease. He related particulars and made general remarks.

Mr. DALE JAMES: A case of Raynaud's Disease.

Dr. RICHARDS (Chesterfield): An album with many striking photographs illustrating Varieties and Stages of the Small-pox Rash.

Dr. ARTHUR HALL: (1) A Brain with Multiple Hæmorrhages, the most conspicuous being a primary ventricular hæmorrhage; and (2) a case of Syphiloderma, which at one time looked so like Scrofuloderma as to be mistaken for it.

Dr. EASTES read notes of a case of Tetanus.—Dr. SORLEY, in discussing Dr. Eastes' paper, related the history of a case of tetanus recently treated at the Sheffield Union Infirmary. The points of interest in the case were the absence of any evidence of injury and the occurrence of a rigor which apparently marked the commencement of the symptoms. There was trismus and marked opisthotonos, but no clinic spasms, unless, perhaps, the occurrence of severe paroxysms of pain beginning in the epigastric region and passing round the body and shooting upwards along the spinal column. Nourishment of a fluid kind was freely taken, and the patient was conscious up to the end, which occurred suddenly in a paroxysm, the patient dying in a rigid attitude. The brain and spinal cord seemed healthy. The whole course of the disease lasted five days. No antitoxin was employed.—Mr. RICHARD FAVELL, Mr. SNELL, and Dr. SINCLAIR WHITE joined in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

The Typhoid Bacillus.

A MEETING of this Section was held on Feb. 19th, Dr. J. M. REDMOND, President, being in the chair.

Dr. MCWEENEY gave an account of some of the most recent researches into the Distribution and Identification of the Typhoid Bacillus. He dealt in the first instance with the results obtained by Dr. Cartwright Wood in his recent experimental investigation of the relation between oysters and the typhoid bacillus. The matter might be summed up as follows. The specific bacilli can remain alive for lengthened periods in sea water, though without multiplying. They can remain alive for lengthened periods in the oyster-fluid, though not in the interior of the oyster itself. At somewhat warm temperatures they can multiply in the fluid of the oyster, and this may happen after removal of the mollusc from the sea during the storage period that precedes consumption. All oysters from beds subject to recent contamination should be condemned. The other research which he described was more recent still, having been published in the current number of the *Annales de l'Institut Pasteur* by Dr. Remlinger and Dr. Schneider, of the French Army Medical Department. Their object was to ascertain whether the typhoid bacillus occurred in nature apart from cases of the disease. They employed Elsner's method for the raw material—soil, water, and fæces of non-typhoid patients—and, in addition to the elevencharacters relied upon by Lösener, they applied the serum test by bringing serum from a horse immunised against Eberth's organism in contact with the organism under examination. With the same object they used the serum of typhoid fever patients. Finally, they inoculated suspected cultures into guinea-pigs with and without protective serum injections. Only when the suspected organism

Hosted by Google

re-acted precisely in the same way as typical typhoid bacilli under the same circumstances did they consider the identification complete. Bacilli answering all the above tests were isolated from various samples of drinking water, soil, and fæces of patients who had never had typhoid fever. The observers were obliged to conclude that the typhoid bacillus is extremely diffused and that it only needs favourable circumstances, such as temporary individual vulnerability, in order to effect a lodgement in the human system. Attacks and epidemics may therefore originate, so to speak, *de novo*—that is, without connexion with any previous case of the disease, which amounted to a re-instatement of Murchison's views. In conclusion Dr. McWeeney demonstrated naked-eye reactions of typhoid serum on the specific bacilli. Tubes prepared by Wright's method were handed round, showing the precipitation of the bacilli by serum from a typhoid fever patient, whilst a central tube treated with a similar amount of non-typhoid serum was turbid owing to the diffusion of the mobile organisms.

Dr. J. W. MOORE believed that all physicians admitted that the eating of oysters might be followed by illnesses that were often accompanied by diarrhœa, high temperature, &c., but were certainly not typical cases of typhoid fever. He had seen two cases of what he called "oyster fever": one was that of a physician who had eaten oysters and in two or three days had symptoms resulting in a fever which certainly was not typhoid fever. The patient recovered in about a fortnight, having had some slight rise of temperature, &c. He believed that oysters were capable of conveying many diseases.

Dr. PARSONS thought the fact stated by Dr. McWeeney with regard to the extreme prevalence of the typhoid bacillus, that in seven out of ten samples of soil typhoid bacilli should have been isolated by the two French experimentalists, was a very astounding one.

Dr. MCWEENEY, in reply, said that he did not question the results of the French experimentalists, because they had worked very diligently and with very great detail, and he thought that their results had been honestly arrived at. It was well known that the tetanus bacillus was very widely distributed. He believed that bacilli bearing a very close resemblance to typhoid bacilli were everywhere around us.

Reviews and Notices of Books.

A Collection of the Published Writings of William Withey Gull, Bart., M.D., F.R.S., Physician to Guy's Hospital. Edited by THEODORE DYKE ACLAND, M.D. Oxon., Physician to St. Thomas's Hospital. London: The New Sydenham Society. 1896.

THE first volume of these collected writings was published in 1894 under the same editorship, and contained the late Sir William Gull's more purely medical works. The present volume contains a memoir commenced by Sir Henry Acland, and finished by the editor with the assistance of Dr. Pye-Smith and others, some fragments, notes and aphorisms, and sundry addresses. The memoir is a well-written and very interesting account of a very remarkable man, for Gull, though modern as far as his science went, was of a cast of mind akin to those seventeenth century thinkers whom he loved so well, Sir Thomas Browne and George Herbert. He was truly a spiritual philosopher, and had the same intense love of nature that characterised Henry Vaughan, also a medical man, the Welsh poet and mystic. Dr. Acland quotes the well-known passage from the "Religio Medici," as a favourite one with Gull and as according well with his feelings, which commences: "At the sight of a crucifix I can dispense with my hat, but scarce with the thought or memory of my Saviour." Two addresses are given upon the Study of Medicine, both delivered at Guy's Hospital—the one in 1855, the other in 1874—and in both the chief canon laid down is that the study of medicine is the study of nature. He rightly lays down a very high ideal as the thing to be aimed at, so high that many of his hearers must have despaired of ever attaining it; but the consciousness of never doing so well as he would wish to do has been the making of many a successful man.

Perhaps the most useful of the addresses to the busy practitioner will be those upon the Collective Investigation of Disease, for the others in the collection, though scholarly, philosophical, and learned, demand more mental application for their comprehension than most men have the leisure or training to provide. The collective investigation of disease was a subject which Gull had deeply at heart and furthered by every means in his power, and though, perhaps, less advance has been made in the thirteen years or so which have elapsed since the addresses were written than he hoped would be the case, still it must be remembered that good and lasting work is invariably slow and that hasty deductions are worse than useless. In the first of these addresses occurs the following passage, which we quote as being eminently characteristic of Gull's way of reconciling apparently contradictory propositions. He is speaking of the help which the general practitioner should give in collective investigation. "It will perhaps be objected, and naturally, that it is almost impossible to organise for any useful purpose the labours of men already overburdened by the cares and fatigue of practice, and that there is neither time nor fitness for delicate inquiries on their part ..... that, further, it cannot be denied that when we see the meaning of the apparent trifles which in practice would otherwise oppress and worry us our burden is thereby much lightened, and that nothing could encourage us more than to feel that even one daily observation recorded was adding to our general store of knowledge and making the path of practice more easy. ..... We, indeed, owe it to those members of our profession who are admittedly overwhelmed by the apparently senseless details of their work to promote a movement like this, the object of which is to bring order into their chaos and to help them to stamp a scientific value upon facts hitherto only burdensome. If we compare the unflagging interest of any pursuit where the aim is high and clear with the tediousness and wearisomeness felt when working in the dark we shall readily admit that we are actually lightening the burdens of practice by thus adding to them, and by giving some portion of them a sense and meaning." This is a passage eminently true, if perhaps somewhat a counsel of perfection, and reminds us of the old statical paradox of preventing a body falling by adding a weight to that side to which it tends to fall, but in both cases the thing is a possibility. Thinkers of every class owe a debt of gratitude to Dr. Acland for the issue of these thoughts of a noble mind.

A Manual of Practical Anatomy. By D. J. CUNNINGHAM, M.D. Edin., F.R.S., Professor of Anatomy and Chirurgery, University of Dublin. Vol. I. Second Edition. Illustrated with Engravings. Edinburgh and London: Young J. Pentland. 1896. Price 12*s.* 6*d.*

AMONG the many excellent manuals of dissections which exist we know of none of which we can speak more highly than of the work before us, and therefore we welcome the appearance of the second edition of the first volume. There are two dangers which have to be avoided by the writer of a manual of practical anatomy. On the one hand, he must refrain from describing so fully the structures exposed that the student is wearied by the description; and on the other, the work must be a great deal more than a mere catalogue of the objects to be seen. There is a far greater tendency to err on the side of excess than in the opposite direction, and the rule should be to describe only so much as can be observed by a student of ordinary intelligence, while the less obvious facts and the more detailed statements find their appropriate place in a work on

Hosted by Google

systematic anatomy. This rule has been observed by Professor Cunningham. The descriptions are careful, and though by no means brief they contain but very little that could be omitted without impairing their completeness. The book represents what may be called the Edinburgh School of Anatomy, though the differences at the present day between the methods of dissection at different medical schools are only slight.

This volume deals with the upper and lower limbs and the abdomen, the description of the thorax and the head and neck being contained in the second volume.

The nomenclature employed is, on the whole, that which is in common use in this country, and the terminology recommended by the committee of the Anatomical Society of Germany in its recently published report has, when different, been added; but there is discernible a slight tendency to the over-use of terms in the Latin form—for instance, the triangle of Petit appears only as the "trigonum Petiti," while the triangle of Hesselbach retains the English form; but, on the other hand, the trigone of the bladder is never called "trigonum vesicæ." Some of the terms recommended by the German Anatomical Committee are decidedly cumbrous, and we can only hope that they will never displace their more common equivalents; thus, "Canalis adductorius Hunteri" is a poor substitute for "Hunter's canal." Also, it is by no means an advance in nomenclature to call both the glenoid and cotyloid ligaments "labrum glenoidale." Professor Cunningham himself seems in doubt as to the value of these additions, as they are not given in the index.

Numerous figures illustrate the text, and we are glad to see that they are diagrammatic; in many recent text-books attempts have been made to represent exactly the appearances to be met with in a dissection. These attempts to be artistic are useless, for a diagram to be of any real value must be diagrammatic, and may on occasion *accentuate* features of importance. Figs. 9, 10, 56, and 88 are good examples of this. A figure which merely represents accurately what can be seen in the dissection is out of place in a work on practical anatomy, for the student should see it in the part dissected and not in the book.

The surgical anatomy is very satisfactory. Especially can we speak with favour of the surgical anatomy of hernia. A very full index concludes the volume.

Microscopic Researches on the Formative Property of Glycogen. Part I. — Physiological. By CHARLES CREIGHTON, M.D. Aberd. London: Adam and Charles Black. 1896. Price 7*s.* 6*d.*

IN this monograph Dr. Creighton describes his microscopic studies in a domain where some of his earlier work was done. The object of his researches is one of some interest: it is to determine to what extent glycogen plays a part in the building up of the animal tissues. The presence of this substance in fœtal and placental structures was known to Claude Bernard, and references to its distribution and possible function as a primordial element have found their way into the writings of physiologists since his day. But we believe that these studies of Dr. Creighton form the most complete and most systematic attempt to interpret the true significance of animal starch. The procedure for its detection in tissues is of the simplest; it consists in the obtaining of the well-known re-action of iodine upon glycogen (the wine-red re-action) to be obtained on microscopic sections of organs and tissues. The general conclusion to which Dr. Creighton has been led by his investigations may best be given in his own words. He says: "Briefly expressed, the formative property of glycogen is analogous to, or parallel with, that of hæmoglobin. Whether animal starch is a derivative of hæmoglobin in the sense in which vegetable starch is a derivative of chlorophyll is a question of chemical origins upon which I do not profess to throw light. But from evidence proceeding upon altogether different lines I have been led to the conclusion that glycogen plays the part of a carrier to the tissues, that it contributes somewhat to the building up without losing its own molecular identity, that it is present at the formation of tissues and employed therein without becoming part of them, and that it acts thus in some cases as the precursor or deputy of hæmoglobin, and until such time as the vascularity of the part is sufficiently advanced, in other cases as the substitute of hæmoglobin from first to last in those tissues which are built up in whole or in part without direct access of blood."

The evidence upon which such conclusions are based has been derived from histological studies of the growth of the bronchial tree, of the kidney, of the choroid, of the intestinal mucosa and of muscle, skeletal and cardiac, among vascular structures; whilst for non-vascular structures the tissues examined comprise the enamel and dentine of teeth, hoof, nail, and hair, and hyaline cartilage. In these latter sites it would distinctly appear that the glycogen plays the part of blood, and it is interesting to observe that in ossifying cartilage the glycogen first appears in spots, which subsequently become centres of ossification. Observations were also made upon glycogen in the placenta and developing mammary gland and also in the fat cells of hibernating animals, this latter forming a new contribution to the physiology of hybernation. The appearances described are well illustrated in the plates that are appended to the text. A second part of the monograph will deal with the pathological side of the question.

LIBRARY TABLE.

Herbal Simples Approved for Modern Uses of Cure. By W. T. FERNIE, M.D. Durh. Bristol: J. Wright and Co. Second Edition. 1897. Price 6*s.*—This enlarged edition of a work we reviewed in our issue of Sept. 21st, 1895, contains a quantity of old-world lore about herbs and plants which is exceedingly interesting. The modern cook knows but little of the many charming dishes of vegetables which our ancestors ate, and the modern housewife nothing. Instead, too, of the cordials and essences which were the delight of our great-grandmothers, people now dose themselves with "Specific No. 1," or "Mother Bunch's Tea," or "Dr. Dee's Boluses for Burdened Believers," or one of the many "amides" or "phenazones" manufactured from coal tar. At one time the "green end of a goose-dropping" was considered a sovereign remedy for fits, and, though scarcely a herbal simple, was preferable to nastinesses sold in bottles with a Government stamp. We are glad to see that Dr. Fernie lauds garlic in cookery, for this excellent bulb is far too little used in our country.

Medicine in Shakespeare. By JOHN MOYES, M.D. Glasg. Glasgow: James Maclehose and Sons. 1896.—This little book is an expansion of a thesis for the Doctorate of Medicine presented to Glasgow University in 1886. The writer died in 1894, and these labours of his appear under the editorship of Dr. James Finlayson. Shakespeare was a genius so many-sided that it is not surprising to find that all his delineations of disease could scarcely be improved upon by a modern physician. The subject of insanity, a disease which the poet pictured with no less vividness than other disorders, Dr. Moyes has left untouched, but he refers to Dr. Bucknill's "Psychology of Shakespeare," published in 1859, and reviewed in our issue of Oct. 15th of that year. Dr. Moyes, however, deals very fully with the other diseases incident to humanity, and has produced a very readable little book.

Hosted by Google

Our Secret Friends and Foes. (Romance of Science Series, Society for Promoting Christian Knowledge.) By P. F. FRANKLAND, F.R.S. Third Edition. Price 3*s*.—Dr. Percy Frankland has here given us an enlarged and revised edition of his book about bacteria written in popular language. In addition to the part played by micro-organisms in the production of diseases, an account is given of their agency in various commercial phases, such as butter-making, brewing, cheese-making, and nitrification. The book can be cordially recommended to anyone desirous of getting a clear idea of the importance of these organisms and of the strides recently made towards a better understanding of their mode of action.

The Management of Infancy. By ANDREW COMBE, M.D. Edited by Sir ARTHUR MITCHELL, K.C.B., M.D. Aberd. Edinburgh and London: Oliphant, Anderson, and Ferrier.—This is an abridgement of the tenth edition of the late Dr. Combe's book, and is published by desire of the Combe trustees, "so as to bring the work easily into the hands of working people." There is no doubt that the matter of the book is admirable, nor is there any doubt that a knowledge of how to manage an infant is sadly to seek among the middle and lower classes; but we rather fancy that the style of this work puts it above the heads of most of those for whom the present edition is intended. Still, the publication of it is an experiment well worth trying.

Musa Medica: A Sheaf of Song and Verse. By J. JOHNSTON, M.D. Edin. London: The Savoy Press. 1897. Price 2*s*. 6*d*.—Dr. Johnston has here published a collection of songs and verses. The former mostly deal with medical subjects, and are well suited for a medical smoking concert — notably, The General Practitioner and John Bolton, C.P. The other verses are concerned with rural sights and sounds.

Everybody's English Song-book, with Melodies. By BASSO. London: Saxon and Co.—A collection of well-known songs, some good and some the reverse, being what Thackeray called "simple appeals to the affections" of the T. H. Bayly school. However, there are one or two gems, such as Waller's "It is not that I love you less," and Ford's "Since first I saw your face."

A Young Congo Missionary. By WILLIAM BROCK. London: H. R. Allenson. Price 1*s*. 6*d*.—The missionary was Sidney Roberts Webb, M.D. He served the office of house surgeon to the Mildmay Mission Hospital for a year, and then proceeded to the Congo under the auspices of the Baptist Missionary Society, where he worked for five years; and, eventually being attacked with black water fever, died and was buried at sea on the way home. The book is a simply told record of a very earnest, self-denying life.

JOURNALS AND REVIEWS.

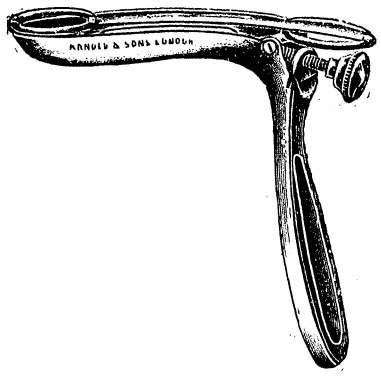
Archives de Physiologie. Fondées par M. BROWN-SÉQUARD. Publiées par MM. BOUCHARD, CHAUVEAU, et MAREY. Cinquième Série, Tome IX., No. 1, Janvier, 1897. Paris: Masson et Cie., Éditeurs.—The following articles are contained in this part. 1. M. J. E. Abelous: Estimation of Reducing Extractives in Organs. 2. M. J. Lefèvre: Variations in the Refrigerant Power of Water in Respect to Temperature and Season: (*a*) On Man. 3. M. N. Paulesco: The Coagulability of Hepatic Blood. The author finds that in fasting dogs there is no difference in point of time of coagulation between the blood of the portal vein, that of the general venous circulation, and that of the hepatic vein, whilst in dogs in full digestion the blood of the hepatic vein coagulates more slowly than that of the vena portæ, and this coagulates more slowly than that of the venous system generally. The quantity of fibrinogen, or, speaking generally, of the globulins, varies but little in these three kinds of blood. 4. M. Alexandre N. Vitzou of Bucharest: New Formation of Nerve Cells in the Monkey's Brain after Complete Ablation of the Occipital Lobes. The conclusions at which the author arrives are that the brain of the young monkey possesses the power of repairing loss of substance and of recovering in part the loss of its anatomical and physiological properties. Thus the recovery of the visual sense lost by ablation of the occipital lobes is due to regeneration of nerve tissue and re-establishment of function. Drawings are given of the appearances seen. 5. M. Bosc and V. Vedel on Free Intravenous Injection of Normal Saline Solution (7 per 1000) in the Treatment of experimentally produced Colibacillary Infection, which they find serviceable, but requiring precaution and care. 6. MM. Piéri et Portier on the Presence of an Oxydase in Certain Tissues of Acephalous Mollusks. 7. Denis Courtade: Contribution to the Rhythmic Function of the Heart. 8 and 9. M. J. Tissot on the Laws of Energetic Movements in Muscles contracting Voluntarily (static contraction) established after the study of respiratory changes, and on the Creation of Elasticity and the Energy which it has Generated in Voluntarily Contracted Muscles. 10. MM. L. Hallion and Ch. Comte on the Form of the "Total Pulse," as indicated by the authors' plethysmograph. 11. M. A. M. Bloch: The Pneumoscope. 12. Dr. W. H. Thompson of Belfast: The Action of Peptone on the Vaso-motor System. He finds that the peptone of De Witte in doses of ten milligrammes per kilogramme of the body weight of the animal lowers the arterial pressure due to peripheral vascular action. It also has an action in the dog on the coagulation of the blood, varying with the quantity administered. 13. M. M. Lambert: The Influence of Cold on the Urinary Secretion. 14. Dr. Alex. Rouxeau: An Account of 103 Operations of Thyroidectomy in the Rabbit, in the course of which he demonstrates that four-fifths of the animals operated on present formidable nervous symptoms indicative of some lesion of the nervous system. 15. M. P. Langlois on Functional Alteration of the Adrenals. 16. MM. E. Wertheimer and L. Lepage on the Movements of the Limbs produced by Stimulation of the corresponding Cerebral Hemisphere. 17. M. A. Charrin: Experimental Epilepsy. 18. Henri Lamy: Medullary Lesions produced Experimentally by Aseptic Embolisms; an important article illustrated by many woodcuts. 19. J. Laudenbach of Kiew: Experiments on the Hæmopoictic Function of the Spleen. 20. MM. S. Dastre and N. Floresco on Fibrin Ferment. 21. M. A. Chauveau: A Criticism on Hirn's Experiments on Thermodynamics and Work.

The *Cornhill Magazine* for March continues its series of Famous Trials, the one for the current number being that of Dr. Pritchard. In most of the famous trials for murder by poison the defendants have been medical men, probably owing to the fact that they have a facility for obtaining poisons which is denied to the ordinary layman, that is to say, as regards the rarer poisons—witness the case of Dr. Lamson. Pritchard, however, used the easily detected poison antimony, as did his fellow criminal Dr. Smethurst—if, indeed, the latter did attempt the crime for which he was tried. Pritchard was perhaps as cold-blooded a scoundrel as ever existed, and in addition to two murders was probably guilty of arson under most aggravated circumstances. For this, however, he was never brought to trial.

In the *Westminster Review* for March Dr. Prosser James has a note upon the Hamilton Association for Providing Trained Male Nurses, an association which provides for a much felt want.

Knowledge.—The contribution to the series of articles on

Hosted by Google



the Science of the Queen's Reign this month is by Hugh Robert Mill, D.Sc., F.R.S. Edin., and deals with the progress of geography during the past sixty years. Dr. Nansen's achievements are noticed in a separate article.

New Inventions.

A NEW COMBINATION SPECULUM.

THE difficulty of keeping the anterior wall of the vagina from obstructing the line of vision while using duck-bill specula must be my excuse for publishing the modification (or rather combination instrument) represented in the illustrations. In nulliparæ it is sometimes no easy matter, even with the patient in the Sims' position, to

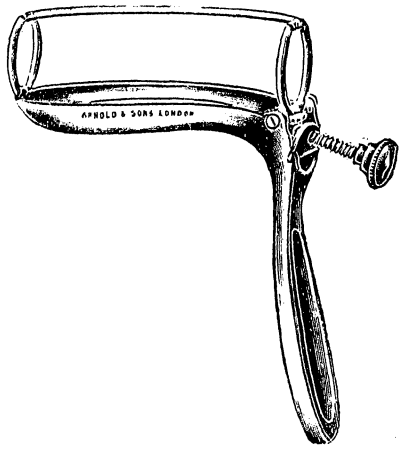


FIG. 1.

Speculum with rings lying flat for introduction.

obtain a clear view of the cervix uteri, the anterior vaginal wall frequently obstructing the view. The illustrations represent the union of my "ring speculum" and Sims' duck bill in one instrument, which can be easily introduced while the rings lie flat; and on turning the screw at the base the rings open at right angles to the duck bill

FIG. 2.

The same with rings upright so as to stretch the vaginal wall.

and force the anterior vaginal wall forward and render the instrument self-retaining. This speculum will be found easier to introduce than the cylindrical speculum of the same size, as all expansion takes place after introduction. The makers are Messrs. Arnold and Sons of Smithfield, London.

Cheltenham. ALEXANDER DUKE, F.R.C.P. Irel.

THE BATTLE OF THE CLUBS.

THE BRADFORD AND DISTRICT MEDICO-ETHICAL SOCIETY.

WE have received a copy of the rules and by-laws of the Bradford and District Medico-Ethical Society. This society has completed twenty-five years of existence, and last year fought and conquered the Bradford School Board over the question of medical certificates. This matter was fully reported in THE LANCET of July 25th and Aug. 2nd, 1896. The action of the society has also brought about that the minimum fee for a club patient shall be 4*s.* per annum. There is nothing very remarkable about the rules, which lay down a standard of conduct such as would be generally approved by the members of an honourable and learned profession, but the suggestions for a scale of fees are, we think, worthy of notice. The principle laid down is the following:—

The general standard is ruled by the average fees charged by the leaders of the profession in any locality. Where the senior practitioners of repute are satisfied with low fees the junior and less known ones are necessarily condemned to accept inadequate remuneration. It is right and expedient that, as is the rule in almost every other profession, increased experience and reputation should bring to the medical practitioner also an increased standard of fees, and not merely a larger number of the small fees with which young and unknown men must be content.

This seems to us to be a very sensible way of looking at things. Those who, like Albert Smith's Mr. Koops, undersell their brethren cannot set a very high value either on their services or the calling they pursue. The following is a portion of the scale of fees decided upon:—

Class.	House rental.			Fee for visit or consultation, to include medicine.					
	£		£	£	s.	d.		£	s. d.
I.	Up	to	25	 0	2	6	to	0	3 6
II.	25	to	50	 0	3	6	to	0	5 0
III.	50	to	75	 0	5	0	to	0	7 6
IV.	75 and upwards, the minimum fee to be 7*s.* 6*d.*								

In exceptional cases the charges for attendance to be at the discretion of the medical attendant.

For each additional patient seen in a house a fee to be charged.

SPECIAL SERVICES.

Such as a first visit or special second visit to be a fee and a half. Night visits—that is, from 10 P.M. to 8 A.M.—a double fee; mileage, beginning two miles from the medical man's house, to be for Class I., 1*s.*; Class II., 2*s.*; Class III., 3*s.*; Class IV., 4*s.* per mile, in addition to the ordinary fee. Sunday visits and consultations to be a fee and a half.

MIDWIFERY FEES.

Class.	£		£	£	s.	d.		£	s. d.
I.	Up	to	25	 1	1	0	to	1	11 6
II.	25	to	50	 1	11	6	to	2	2 0
III.	50	to	75	 2	2	0	to	4	4 0
IV.	75	to	100	 4	4	0	to	5	5 0

In cases of very poor people with house rents less than 4*s.* 6*d.* a week the midwifery fee to be 15*s.*, if paid at the time (except in first cases); if not, to be 21*s.* Extra midwifery services, such as turning, forceps, craniotomy, removing retained placenta, &c., to be a fee and a half. Visits to midwifery cases not completed in twenty-four hours from the first visit to be charged for as ordinary visits.

DOCKYARD MEDICAL CLUB, PORTSMOUTH.

At the annual general meeting of the Portsmouth Dockyard Medical Benefit Society, held recently in St. Faith's Mission Hall, Landport, one of the speakers was so kind as to confirm our statements that lay managers of these clubs do not behave fairly or politely to their medical officers. In moving the adoption of the report this person said that the society ought to have the whip hand of the medical officers and let them see that they were the servants of the society. One of the medical gentlemen had taken exception to certain members being allowed to belong to the society, expressing the opinion "that it was not right for many of the members who were possibly better off financially than himself to be allowed to remain in the society, and he thought some scheme could be arranged to exclude this class of members." This, said the speaker, was dictating as to who should and who should not belong to the society.

Hosted by Google

THE LANCET.

LONDON: SATURDAY, MARCH 13, 1897.

DR. CULLINGWORTH did not err in the choice of a subject for his opening address as President of the Obstetrical Society. There is no greater joy to medical men than for one of their number to point out *desiderata* in therapeutics and the means of their accomplishment. And there is no one department of practice in regard to which such service is more acceptable than the obstetric department. The profession has pretty well agreed that puerperal fever can generally be prevented, and every contribution made on good grounds and in good judgment towards this end by a teacher or a practitioner of medicine is to be received with thankfulness.

Dr. CULLINGWORTH illustrates his subject somewhat differently from those who have in various ways taught us the same lesson. Like Sir JOHN WILLIAMS, Dr. BOXALL, and Dr. GODSON, he founds his argument on the experience of the lying-in hospitals, the existence of which was seriously threatened as being hopeless foci of puerperal fever, but which by dint of diligent and thorough use of antiseptics—notably of the perchloride of mercury—have been practically cleared of this pest. He then goes on to compare with this state of things the continued, almost the increasing, prevalence of puerperal fever in private practice. He selected for illustration certain districts of the country where the facts have been specially made out or where the undue prevalence of puerperal fever strikes the student of such questions. There is one significant point to be noted in this and in other discourses of the kind—the admission that in respect of deaths from what are called the accidents of childbirth as distinguished from deaths from puerperal fever (that is, from hæmorrhage, eclampsia, puerperal mania, embolism, &c.) there is a diminution in both London and the provinces, especially in London. This is a most satisfactory revelation, and shows that in respect of obstetric education and art there is a decided advance of late years. But the fact only makes it the more remarkable that there should not be a corresponding improvement in the mortality from puerperal fever. The difference, or what we may call the inconsistency, is so curious that we are almost led to suspect that there must be fallacy in the figures or in the way of using them. It is scarcely credible that new generations of medical students are being so trained as to be more skilful in dealing with the accidents of childbirth and less so in the use of a douche and other comparatively simple precautions that are to avert "death and all the sad variety of pain" covered by the expression "puerperal fever." This aspect of the case requires a little more attention than it has received. Whatever may be the explanation of this inconsistency, let us look at the statements of Dr. CULLINGWORTH. He deals impartially with all classes affected by his statistics—whether midwives or medical men, and whether residing in the provinces or in the metropolis, in the East-end or in Hampstead. We give him credit for the simple desire to get at facts and to carry the improvement of midwifery and the fame of medicine to their highest points. He sets forth the districts in which puerperal fever or mortality from it is highest. Unfortunately he does not always deal with the same sort of statistics in comparing different parts. Thus, in regard to provincial districts he deals chiefly with mortality from puerperal fever, while in respect of London he supplies and reasons from the mere notifications of the disease. True, he says that the conclusions would come out much the same, but there is a great difference between notifying a case of puerperal fever and a death from puerperal fever. What is puerperal fever? Is any pyrexia in the puerperal period to be dignified with this epithet? Clearly there is much ground for vagueness and unreliableness in the mere notification of cases. One man, not necessarily with more candour than another, but with less decision and less power of definition, may notify a passing pyrexia as puerperal fever which another would regard as one of the many febriculæ to which the lying-in woman is exposed on the slightest provocation. The statistics concerning London are based on the *notifications* of puerperal fever kindly supplied to Dr. CULLINGWORTH by Mr. SHIRLEY MURPHY, medical officer of health of the Administrative County of London. They bring out the fact that puerperal fever is noticeably prevalent in some of the better parts of London. Thus Hampstead, with its comfortable villa population and the Heath in proximity, heads the list. Islington is not much better, and its best and least populated part has most cases. On the other hand, this is a very densely populated parish and has more excuse than Hampstead for such cases. But why should its best parts have more cases? Here we may suppose that a report of *deaths* would be corrective of a report of mere notifications. "For its size," Mr. HARRIS, the medical officer of health, in his report for 1895, says, "the parish is remarkably healthy." He reports twelve deaths from puerperal fever in 1895, or 1·21 per 1000 births; the mean rate for England and Wales is 2·0 per 1000 births. No doubt, according to present and most wholesome doctrine, 1·21 per 1000 is 1·21 per 1000 too many; but it is a very different thing from 3 per 1000, the notification number as given by Dr. CULLINGWORTH. But it is in the provinces that the mortality returns are most serious, especially in some parts of Wales and in Lancashire. In the Pontypridd district it is 4·1 per 1000. In the Merthyr Tydvil district it is 4·7 per 1000. In the Bridgend district it is 4·5 per 1000. In the Haydock district of Lancashire the mortality is excessive. In all these districts the majority of cases are attended by midwives, mostly untrained and grossly ignorant. In Haydock the medical officer of health, Dr. HAYWARD, avers that scarcely one-fifth are attended by medical men, and, it must be added, the districts are insanitary.

To bring all such facts into the light of the clearest criticism is the plainest duty of medical teachers and medical journalists, and the paper on which we have commented should receive the anxious attention of every practitioner.

Hosted by Google

We cannot help suspecting that there are some fallacies in the presentation of this subject. It is inconceivable that private practitioners should be less careful of antiseptic precautions than they were ten or twenty years ago. The contrary is notorious. Yet this is the assumption required by the prevalent doctrine of obstetric teachers. But of one thing we are certain—namely, that the practitioners of the country will consent to no permanent superiority in the results of lying-in hospital practice as compared with their own.

AT the present time, when we read of the action of certain European Powers in respect to cargoes of cotton from plague-invaded ports, it may not be out of place to inquire briefly upon what evidence this fear of the importation of plague through the agency of such articles as cotton or wool is based. It is an easy matter to assume that when an infectious disease is prevalent within any given district there may be fear of such disease being conveyed through the agency of merchandise from the invaded centre; but when we ask upon what evidence this fear is based we are not so easily supplied with an answer which is proof against destructive criticism. We read in the text-books of plague having been conveyed from one place to another through the agency of bales of cotton or wool, but the evidence which is given as supporting this statement is as a rule somewhat scanty. Indeed, it seems that when some of these questions are approached in a spirit of unbiased inquiry there is but little evidence tending to support the text-book statements. For instance, among European nations the French are not behindhand in their dread of the importation of infection through the agency of certain merchandise from infected Indian ports, but it does not seem that the French in taking up this attitude, are mindful of a certain Report which was made to the French Government in 1846 by a Special Commission appointed by the French Academy of Medicine upon this very subject, and which Report was brought before the Lord President of the Privy Council by Sir JOHN SIMON in 1875.

In bringing forward the evidence adduced in this Report Sir JOHN SIMON pointed out that Western Europe had not suffered from plague for more than 150 years, and that up till quite recently the disease had been frequent in the Levant, from which plague-invaded district wool had in all times been exported without apparently any case of plague having been caused thereby. Allegations, dating from 150 to 200 years back, that merchandise from plague-infected districts had carried infection are not, Sir JOHN SIMON observes, such as can be accepted in the present day (1875) without much careful scientific sifting; and against the probability of these statements having any basis in fact there is not only the negative evidence just referred to, but also the delivery of the Commission of 1846. The delivery was as follows: "Rien ne prouve que les marchandises puissent transporter la peste hors des foyers épidémiques"; and the arguments upon which this conclusion was based were there: "En 1835 la peste épidémique sévissait à Alexandrie sur les employés de tout grade habitant dans les magasins du gouvernement Egyptien. Cependant une très grande quantité de balles de coton journellement maniées par les hommes de peine furent expédiées de janvier à juin, c'est-à-dire pendant toute la durée de l'épidémie, dans tous les grands ports de l'Europe sans qu'il en résultât aucun accident de peste. Il en fut porté en 1835: en Angleterre, 31,709 balles; à Marseille, 33,812; à Livourne, 424; en Hollande, 150; à Trieste, 32,263; dans divers ports, 32. Ces balles de coton, nous le répétons, ne donnèrent la peste à personne, quoique aucune précaution n'eût été prise pour les désinfecter. Soumises à la presse, en dehors du navire, elles étaient ensuite entassées dans un espace aussi étroit que possible; les écoutilles étaient fermées, et on expédiait ainsi le navire. Sur 16 navires anglais chargés de coton qui quittèrent Alexandrie du commencement du janvier à la fin de juin, 8 eurent la peste à bord, et cependant le coton chargé sur ces navires ne fut pas plus dangereux que celui des navires non infectés. Nous terminerons, messieurs, ce que nous avions à dire sur la transmissibilité de la peste par les marchandises, en arrêtant votre attention sur un fait d'une grande portée, et qui est positivement et officiellement reconnu. Depuis 1720, aucun des portefaix employés dans le lazaret de Marseille au déchargement et au maniement des marchandises n'a contracté la peste." Sir JOHN SIMON thus concluded his report: "Under these circumstances I evidently have no facts which would justify me in stating it to be necessary for the public safety that wool or other merchandise from Eastern places infected with plague should be excluded from this country."

We are far from asserting that it is impossible for plague when its virus is in a certain phase of activity to be conveyed through the agency of cotton or wool, but in endeavouring to arrive at any conclusion on this question the very important negative evidence furnished above should receive its due share of consideration; and it is to be regretted that articles on plague in the text-books are, for the most part, silent as to the conclusions of the French Commission, although at least sufficient prominence is given to "reports" in the other direction. If action were taken upon the statements contained in some of the text-books, it is conceivable that under certain circumstances much misery might be produced in some of the manufacturing districts of England, loss and misery which would be, perhaps, hardly justified upon the evidence obtainable upon this point.

THE important question as to the share taken in the spread of diphtheria by the aggregation of children in the public elementary schools is one upon which a marked difference of opinion exists between the medical officers of the Administrative County of London and of the London School Board respectively. Upon the general thesis as to the liability of this, as of other infectious diseases, to be disseminated by this means there is no room for disagreement, the proposition is self-evident. The persistence of diphtheria in the metropolis, its steady yearly increase, and its fateful roll of child mortality does, however, most urgently demand the determination of the extent to which school influence operates. Mr. SHIRLEY MURPHY'S careful and impartial studies of this subject have led him to the very definite conclusion that the school factor is one of the chief agencies to be considered in the search for

Hosted by Google

a rational explanation of the extension of this disease. He has shown how the tendency of diphtheria to attack in undue proportion children of "school age" has increased *pari passu* with the increase of elementary schools, and, further, that during the period when schools are closed for the holidays there is so marked a decline in the incidence and mortality from the disease as to compel the conclusion that school attendance has much to do with its spread. It is needless to dwell upon the gravity of such a conclusion, which cannot be dismissed without a thorough investigation, one too that places a heavy responsibility on those directing such schools in respect to the provisions they make for preventing the spread of infection. The special report made by Dr. W. R. SMITH at the request of the School Board in April, 1896, was an attempt to show that the spread of diphtheria in London could not be explained on the ground of the increasing liabilities to infection at schools, the multiplication of which, on the first hypothesis, would mean the multiplication of foci of infection. He did not limit himself to London, but supported his argument by an appeal to the variable distribution of diphtheria in all parts of the country and at different periods of years, contrasting this with similar changes in the geographical distribution of other specific infectious diseases. Dr. SMITH holds that age, *per se*, is the chief factor to be considered, and that the age incidence of the disease commences earlier than the school age period, whilst he maintains that there is comparatively little direct evidence of infection at schools. He does not, however, appear to observe that the age incidence has changed with increase of school attendance.

This conflict of opinion on a matter of such importance to the community has now been brought within a narrower compass in connexion with an outbreak of diphtheria which occurred at Lewisham in the course of last year. Here, at any rate, we have a concrete instance wherein the question of school influence is capable of being put to the test; and we have before us certain documents that enable an opinion to be formed upon it. These consist of (*a*) a report, dated Nov. 16th, 1896, of the medical officer of health of the Administrative County of London presenting a report of Dr. HAMER on the outbreak in question, and (*b*) a report, dated January, 1897, of the medical officer to the London School Board dealing with the preceding. We do not propose to enter minutely into the details discussed in these papers, especially as the question has still to be dealt with by the County Council; but in view of more recent outbreaks in Camberwell and Wandsworth, in both of which places infection through school attendance has been highly probable, we feel it incumbent to direct attention to them without delay. The outbreak was limited to a small area of the Lewisham district, about a quarter of a mile square, and having a population of 7882 persons in March, 1896. During 1895 and the first half of 1896 there had been a disproportionate incidence of diphtheria upon this area, but from the twenty-seventh to the forty-fourth weeks of 1896 this disproportion was excessive — no fewer than 108 cases occurring within this small part of Lewisham out of 158 for the whole district. Dr. HAMER found that the disease attacked children of school age in undue proportion, for whereas in the period from 1893 to the thirty-sixth week of 1896 the relative incidence on children aged three to twelve years was 58·5 per cent. of all attacked, from the thirty-sixth to the forty-fourth week of 1896 it was 73·6 per cent. He also showed that the comparative mortality at school age was higher by one-third in this "affected area" during the period named than it was for the whole of London in the years 1893–95. Analysing the facts more closely he showed that amongst families who were attacked the *first* to suffer were to be found in greater proportion at this school-age period, and that the proportion of such children ("first sufferers") was higher amongst attendants at the two chief schools of the district (the Lewisham Bridge Board School and the National School) than amongst those attending other schools or no school at all. He further found that particular classes in these schools yielded these cases; and including cases of sore-throat, which were known to precede diphtheria in a family, he was able to show that during the weeks named there was every ground for attributing much of the disease to school infection. Dr. SMITH traverses the arguments adduced by Dr. HAMER in almost every particular, but unfortunately he does not appear to have covered quite the same ground, so that the statistics of the two reporters are not strictly comparable. There is, however, one point which is most material to the issue that seems to have been ignored by Dr. SMITH, and that is in respect to the chances of infection, not among classmates only, but amongst the school children generally; whilst his conclusions—that, of 137 cases, in 116 the evidence is such as to exclude the school as the source of infection, and in the remaining 21 the evidence of such infection is insufficient—are quite at variance with those arrived at by Dr. HAMER.

It is, we think, much to be regretted that the medical officer of the School Board should have adopted so inflexible an attitude in respect to this question; nor can we agree with him that closing a school or certain classes in it where infection is probable would not diminish the risks of the spread of the disease. But, of course, if he adopts the view that the incidence of diphtheria upon school children is merely a fortuitous circumstance due to age influence and not to school infection, it is useless to attempt to convince him on the point. Meanwhile diphtheria spreads in the metropolis, and one potent factor in its spread, according to general opinion, is suffered to remain untouched. It is a serious responsibility that is thus entailed on those in authority, with whom may rest the power to check the course of this scourge of modern life and so prevent the sacrifice of the lives of many children.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—The annual general meeting of the Royal Westminster Ophthalmic Hospital was held on the premises on March 5th, Sir Charles Turner presiding. The report showed that during last year there were 558 in-patients, the number having been 468 in the preceding year; there were also 10,301 new out-patients and the total attendances of out-patients were over 28,000. The income was £2251 and the expenditure £2386. The chairman pointed out that the building fund, which had now been open for three years, had strong claims on the charitable public.

Annotations.

"Ne quid nimis."

THE CHOICE OF AN ANTISEPTIC IN MIDWIFERY.

WE publish in another column a letter from a practitioner signing himself "Antiseptic" and asking for information on various points as regards the use of antiseptics in midwifery. "Antiseptic" refers especially to the antiseptics he has himself used for washing out the uterus. We should like, in the first place, to emphasise the point that the fundamentally essential thing in applying the principles of antiseptics in the practice of midwifery is the thorough disinfection of everything that is to come into contact with the patient, more especially the hands of the attendant, before touching her. There are, of course, occasions on which it is necessary to wash out the uterus. But the washing out of the uterus after labour is only exceptionally necessary, and is certainly not part of the regular routine that should be adopted in every case in order to avoid the risk of puerperal fever. The same is true of vaginal douching after delivery. We suppose, although it is not stated in our correspondent's letter, it is rather with regard to deciding which is the best antiseptic to use for disinfecting the hands that he wishes for information. The three agents he mentions are mercuric chloride, mercuric iodide, and carbolic acid. There can be no doubt that, as regards practical results, much more depends on the thoroughness of the cleansing, followed by disinfection of the hands, than on the choice of this or that antiseptic from the above list. Certainly the great improvement as regards both morbidity and mortality in lying-in hospitals has been obtained with perchloride of mercury. It is stated, however, in Norris's "American Text-book of Obstetrics" that "some large clinics, such as those of Copenhagen and Vienna, yet cling to the use of carbolic acid, and obtain just as good results as those in which this drug has been supplanted by bichloride of mercury." The truth is that the personal factor must be remembered, as on this as well as on the particular antiseptic employed depends the thoroughness of the disinfection. We wonder if "Antiseptic" can call to mind his early experiences in the class of practical chemistry. For ourselves, we remember well that often after the lecturer had carefully described and performed the steps of some simple test there were almost always some members of the class who could not get the test to "come off," or who obtained some physical phenomena altogether different from what should have resulted, according to the teacher's description and demonstration. And what was the explanation? Why, in a large number of cases, simply dirty test-tubes. The student had not sufficiently washed his test-tube, or perhaps had failed to give it the final washing with distilled water before trying the test. The application of this illustration to the question of personal disinfection is obvious. With the same reagents and apparatus failure may result from want of thoroughness in practically performing the steps of what may rightly enough in many cases be regarded as a test. When the test does not give the desired result, or, in other words, when symptoms of puerperal septicæmia arise, the blame is not due to the antiseptic, if it be one of the three given by our correspondent, but rather to a want of thoroughness in using it. As between perchloride of mercury and mercuric iodide, the latter is much more expensive than the former, while perchloride of mercury has been clearly shown to have at all events so much efficiency that by properly using it for the hands the safety of the patient is practically secured. As a matter of detail, many prefer to use iodine water (two drachms of tincture of iodine to a pint of water) for washing out the uterus when, exceptionally, this may be required. We are inclined to regard it as a safer agent for the purpose than either perchloride of mercury or carbolic acid.

BEES IN MEDICINE.

WHEREVER the bee has found a home honey has almost invariably been used both for food and medicine. From the papyri we know that honey played not an unimportant part in the composition of many of the Egyptian medical potions, and H.H. Sir Bhagvat Sinh Jee, M.D., has told us in his recently issued History of Aryan Medicine, the *rôle* which honey took in the native pharmacopœia of India. Among the medical writers of the past who have alluded to its use may be mentioned Hippocrates and Galen. In the current issue of the *St. Bartholomew's Hospital Journal* Mr. John Gutch gives some interesting gleanings from old writers who have mentioned bees and honey in a therapeutic connexion. Although honey has been used as a medicament, it is not perhaps generally known that not only the sweet product of the bee, but the bee itself has been used in therapeutics. According to the author of the article quoted above, bees drowned in honey have been recommended for clearing the eyes, for staying vomiting, and as useful also for deafness. The curious injunction is given when using the medicine for clearing the eyes that the patient is to be bound, for such is the violence of the medicine that he cannot otherwise patiently endure it. The following remedy is given by Celsus: "The bodies of bees taken newly from the comb and powdered and drunk with Dierretick wine powerfully cures dropsy."

THE THERAPEUTICS OF THE GOOD SAMARITAN

IN last week's Parliamentary debate on the Greco-Turkish imbroglio the action of Greece in coming to the rescue of her Cretan compatriots was likened by the Leader of the Opposition to that of the Good Samaritan who relieved the wounded victim of highway robbery after the priest and Levite—typifying the Concert of Europe—had passed on unregardful of his sufferings. With the political application of the parable we have nothing to do any more than with the retort of the Leader of the House that the Good Samaritan would not have been admired for eighteen centuries if as a result of his intervention he had added largely to his personal estate. Our interest in the parable lies in its medico-historical aspect—in the treatment to which the wounded man was subjected and in the light it throws on first-century practice. The parable, we need hardly remind our readers, comes to us on the authority of what M. Renan calls "le plus beau livre qu'il y ait"—the most beautiful book in all literature—the work, we may add, of a Physician whose familiarity with Hippocrates has been proved by Hobart and Plumptre, and whose practice seems to have lain, at least for one memorable period, in the mercantile marine of the Mediterranean. Till recently the only version of the parable accessible to English readers represented this capable practitioner as reporting the Good Samaritan to have bandaged the victim's wounds—incised, punctured, or lacerated—and then to have poured into them oil and wine. That mistranslation continued to puzzle generations of the devout till the Revised Version put matters right by substituting "pouring on" for "pouring in"—the Authorised rendering having been adopted from a misinterpretation of the Vulgate, which gives "infundens" as the equivalent of St. Luke's ἐπιχέων, though "infundo" means to "pour upon" as well as to "pour into." The Good Samaritan's therapeutics are thus vindicated as conforming to the recognised practice of the time, whether Greek or Jewish. The bandage having been adjusted, it was saturated with a mixture of oil and wine,

Hosted by Google

an emollient and a stimulant, presumably to keep the cloth from stiffening while rousing the reparative or healing process. It was the practice employed in circumcision, as we read in the rule: "If there is no mixed oil and wine ready each may be added separately." Galen, writing about a hundred and thirty years subsequently to St. Luke, describes a paste, in which oil and wine are the principal ingredients, to be applied to wounds. The Elder Pliny, whose "Historia Naturalis" was nearly contemporary with St. Luke's Gospel, refers to the same practice. The Good Samaritan's therapeutics, as reported by St. Luke, were, indeed, *secundum artem;* and if they have caused any difficulty to the non-classical reader, that has been removed by the revisionist substitution of "pouring on" for the meaningless "pouring in."

PRESERVATIVES IN PHARMACY.

AN interesting and thoroughly practical paper on the Preservatives of Pharmacopœial Preparations was read before the Pharmaceutical Society by Mr. William Martindale on March 9th. Alcohol, he said, is not a germicide; when present to the extent of 20 per cent. by volume of absolute alcohol it has an inhibitory effect on the germination of most of the micro-organisms occurring in aqueous solutions of vegetable and animal substances, but the germs propagate readily as soon as it evaporates. Salicylic acid is the preservative employed for the official solution of hydrochlorate of cocaine, which contains 1½ per mille of the acid, with 10 per cent. of the cocaine salt. This solution, even if diluted with four times its volume of water, still keeps free from the fungoid growths to which cocaine solutions are so liable. Salicylic acid, however, cannot be added to solutions of either morphia or apomorphia intended for hypodermic use as it causes the formation of a crystalline deposit. Mr. Martindale's address contained some valuable suggestions on the preparation of dilute mercurial solutions. He especially objected to the addition of chloride of ammonium to solutions of corrosive sublimate, on the ground that white precipitate is liable to be deposited on dilution with common water, and most of the mercury may in time be withdrawn from the solution.

THE CONDITION OF CONVICTS IN THE PRISONS OF NEW YORK STATE.

THE Legislature of New York State have lately passed a law enacting that the convicts in their prisons shall not be allowed to work while under sentence at any trade or occupation whereby they may compete in any way with free labour. This state of affairs was brought about by the action of the American Federation of Labour, and practically condemns the convicts to solitary confinement. The effect of this law, even within the short time it has been in force, has proved most injurious to the health of the prisoners. Already a man who was confined in Sing-Sing has committed suicide as the result of the influence of compulsory idleness, and the authorities are at their wit's end to devise means of remedy for this unfortunate situation. As the law now stands the convicts are not allowed to do any description of work for the State. Exception is taken to such occupations as printing and bookbinding, and fault is even found with printing for the use of the prisoners only; in fact, their sole distraction is the exercise which they are allowed to take for a short time daily. It has been suggested that the men be taken out and put on the public roads improvements and fortifications, as is the custom in England, but there are so many difficulties in the way that this suggestion is declared to be unworkable. A long term of isolation has been conclusively proved to be hurtful in a high degree both to the mind and body of a man; it was found in England after the system had been thoroughly tested that long periods of solitary confinement weakened the minds of the convicts. In America some critics contend that the moral efficacy of any period of strict separate confinement is more than doubtful, and go so far as to assert in the present case that unless some measures are taken to give the prisoners work to occupy their time more asylums for insane criminals must be built. After all is said and done the object of criminal punishment is not vengeance but the improvement of the offender, and besides it is surely punishment to a lazy man to be compelled to work, to a drunkard to be compelled to keep sober, and to a dissolute man to be compelled to lead a clean life. The true conception of a prison, as we take it, is that of a hospital for the remedial treatment of depraved bodies and diseased minds. The mere temporary caging of the criminal like a wild beast is a protection to society for a time, but it is only for the time being; for when he is let out he is in most instances more dangerous to society than when he went in. The criminal should be treated as a man, and not as a wild beast. No one is in any way benefited by driving convicts crazy and making their lives miserable and useless. Humanity and sound economy both dictate that prisoners shall be engaged daily at something which will occupy their time and energies, and it is not enough that criminal jurisprudence should be humane, it should also be intelligent. The prisons and reformatories of New York State have for a long time taken high rank amongst like institutions in different parts of the world for the humane and intelligent manner in which they have treated their prisoners—in fact, in many respects they have acted as pioneers, and it is to be hoped that the present deadlock may be but temporary.

STILL THEY COME!

MESSRS. GUY, Beecham, Seigel, Page Woodcock, Williams, Hood, Clarke, and the rest of the nostrum-selling fraternity will have to take a back seat. A new constellation has arisen. We have seen the following statements in print, so they must be true! They are sworn to before solicitors, and the attestor in one case is a publican and in the other a schoolmaster; moreover, we regret to add, a parish schoolmaster. He has for nine years been suffering from pains in the stomach and bowels. The pain was of the most "excrutiating" (*sic*) nature, and night after night he was killed with a pain that doubled him up in the most painful manner. He had scores of bottles of doctors' medicine, with the same result—no relief, but constant pain. He also had a very serious case of bleeding from a bloodvessel bursting at the bottom of his stomach, and on Oct. 30th, 1896, he read one of Messrs. Forshaw and Snow's circulars and entered their shop. Here Mr. Forshaw at once "told me what I ailed—viz., inflammation of the mucous membrane of the stomach. He told me more than this—viz., that he could cure me. I determined to place myself in his hands, and he gave me a course of his excellent Infirmary Pharmacy Blood Purifier and Stomach Mixture and Digestive Extract. I went home and can honestly say that from the first moment I took the first dose of his mixtures I have never had one single moment of pain. Why is this? Simply because Messrs. Forshaw and Snow understood my case, and knew what would do me good and gave me it." The publican was in even worse plight. Instead of being killed every night, "life to me was becoming a burden, and every day became longer and my sufferings more severe." He was not content with bottles of doctors' medicine, but "went on trying first one doctor then another till I was as weak as a child." Then a light arose in the darkness and he read one of Messrs. Forshaw and Snow's pamphlets, and after taking one bottle of the Infirmary Pharmacy, &c, and a few doses more he was happy, cheerful, and full of fun and life. We may remark that the Infirmary Pharmacy has

Hosted by Google

nothing to do with the Bradford Infirmary, although the active partner in the firm, we are informed, used to be dispenser at the infirmary. We have not the least doubt that both publican and schoolmaster could have got the identical mixture at the infirmary, only it would not have been called such a long name, and, of course, would not have been puffed in pamphlets "left on the bar window." The rejoicing sufferers whose story is here set forth live in Bradford. Now at Leicester we expect this kind of thing, but that Yorkshiremen should be so confiding is remarkable.

THE ROENTGEN RAYS AS A DEPILATORY.

NUMEROUS writers, both in Europe and America, have published accounts of the injurious effects produced on the skin by a too prolonged exposure to the Roentgen rays, the symptoms varying in nature and intensity from "sunburn" to dermatitis, vesication, and ulceration. Loosening of the hair, sometimes carried so far as to result in baldness, was frequently observed, and this peculiar property of the rays has been ingeniously turned to useful account by Dr. Leopold Freund of Vienna in the case of a child, four years of age, who suffered from a pigmented hairy nævus covering almost the whole of the back. The patient's neck was in the first instance submitted to the action of the rays, and after ten exposures lasting two hours each the hair commenced to fall out, apparently in consequence of atrophy of the bulbs. Eight days later dermatitis was first observed. The child was shown at a recent meeting of the Gesellschaft der Aerzte of Vienna six weeks after the discontinuance of the treatment, and all the parts which had been exposed to the rays were then quite devoid of hair. The rays only act in this particular manner by slow degrees, from nine to twelve days being required for the development of the effect. It was found that the hair of the scalp was more easily attacked by the rays than the abnormal hair of the pigmented nævus. There is much reason to suppose that the Roentgen rays may therefore be a valuable addition to our methods of treating hypertrichiasis. In the course of the discussion on this case Professor Kaposi suggested that the first stage of the action consisted in the rays irritating the deeper bloodvessels of the skin, and that the hair subsequently came out in consequence of the nutrition of the skin being thus interfered with. He also remarked that the dermatitis caused by the Roentgen rays resembles that from which Alpine climbers suffer after exposure to the glare of sunshine reflected from snow or glaciers.

PHYSIOLOGICAL INFLUENCE OF MUSIC.

MM. BINET and J. COURTIER give in the *Revue Scientifique* an account of experiments made by themselves and others on human beings and animals of the effects of music on the heart and respiration. M. Patrizi, an Italian physiologist, had a patient with a wound in the skull which laid bare the brain. He was thus enabled to observe the actual effect of music on the cerebral circulation. Music occasioned an increase in the size of the brain itself. The effect on the cerebral circulation was variable, the vessels being sometimes constricted and sometimes dilated. At other times no effect was produced. MM. Binet and Courtier experimented on a musician. Isolated notes, chords in unison, and discords were first tried. Both major chords struck in a lively manner and discords quickened the respiration, the latter more especially. Minor chords tended to retard respiration. When melodies were tried it was found that all, whether grave or gay, produced quickened respiration and increased action of the heart. The lively tunes produced the greatest acceleration. The subject also sometimes unconsciously endeavoured to synchronise his respirations with those of the singer. In *rallentando* and *diminuendo* passages the respiration was retarded. Where the sound was wholly uncomplicated by emotional ideas, as in single notes or chords, the heart's action was accelerated, but not in so marked a degree as when a melody either grave or gay was played. During operatic pieces or those well known to the subject the acceleration attained its maximum. The subject had a strongly marked capillary pulse. The influence of music on the capillary circulation was tested by a plethysmograph attached to the right hand. The capillary tracing usually showed a diminution of pulsation. This diminution was occasioned by the sound of single notes, chords, or discords. In sad melodies, especially minor ones there was almost no diminution, whilst in lively airs the diminution was marked.

THE REGISTERS OF MEDICAL PRACTITIONERS AND OF MEDICAL STUDENTS.

THOSE who are interested in the numbers of medical men will like to know that the Medical Register and the Register of Medical Students for the year 1897 are now published and may be obtained from the publishers, Messrs. Spottiswoode and Co., 54, Gracechurch-street. As regards the principal facts of the Medical Register for 1897 they have been already published by us, through the kindness of the Assistant Registrar, on Feb. 6th. Speaking summarily, they show that the new registrations in 1896 were 1385, as compared with 1446 in the preceding year. Nevertheless, the numbers on the present Medical Register are 34,478, as compared with 33,601 in the preceding year. Coming to the new registrations of medical students in 1896, and therefore in the Register now published, we find them to be 1741, as compared with 1838 in 1895. Of these registrations 919 were in England, 557 in Scotland, and 265 in Ireland. The respective Registers are full of various information and carefully prepared tables. They supply much material for reflection, and certainly none for anxiety as to the supply of medical men. Not the least interesting part of the Students' Register is the names of the various schools from which the students date as commencing medical study.

THE MEDICAL SOCIETY OF LONDON.

THE Medical Society of London celebrated its 124th anniversary on Saturday, March 6th, by a dinner in the Whitehall Rooms of the Hôtel Métropole. The President, Mr. Reginald Harrison, occupied the chair, and 130 Fellows and guests were present. Among the latter were Lord Lister, President of the Royal Society; Sir William MacCormac, President of the Royal College of Surgeons; Dr. Dickinson, President of the Royal Medical and Chirurgical Society of London; Mr. Butlin, President of the Pathological Society; Dr. Savage, President of the Neurological Society; Mr. Bigham, Q.C., M.P., Mr. Lawson Walton, Q.C., M.P., Professor Bridge, Sir William Mackinnon, Sir J. Crichton Browne, Sir William Dalby, Sir Dyce Duckworth, Sir William Roberts, and Dr. Farquharson, M.P. The toast of "The Sister Societies" was proposed in a humorous speech by Mr. Frederick Treves. Lord Lister, in rising to respond, received an enthusiastic ovation, and in referring to the peerage which Her Majesty had conferred upon him he said that it was an honour entirely unsought by him, and that in fact he was not asked beforehand if he would accept the honour. The kind way in which the members of his own profession had hailed his admission to the House of Lords had been inexpressibly gratifying to him. Sir William Dalby, in proposing the toast of "The Visitors" twice "brought down the house," first by his graceful congratulations to Sir William MacCormac on his recovery from his recent illness, and afterwards by a sympathetic allusion to the "cruel persecution" to which Dr. Cullingworth had been subjected. The toast was responded to by

Hosted by Google

Mr. Butlin and Mr. Bigham. A capital musical programme was provided, and the dinner was one of the most successful in recent years. The Royal Medical and Chirurgical Society last year instituted a dinner which promises to be an annual function, and the other societies might well occasionally imitate the example thus set them by their elders.

THE PREVENTION OF TUBERCULOSIS IN NEW YORK.

THE Health Department of New York has taken the step of declaring pulmonary tuberculosis to be an "infectious and communicable disease dangerous to the public health." It has also ordained that notification of each case of the disease coming under the notice of medical practitioners in the city shall be made within a week of its first coming to the knowledge of the practitioners, and that public and private institutions and dispensaries shall also notify all cases heard of; but how far the duty is to be one for which remuneration is to be given is not stated. The provision of hospital accommodation for the poor suffering from the disease is enjoined by the medical members of the department, these poor sufferers being regarded as active sources of danger to the community. All institutions taking in cases of the malady are to be systematically and officially inspected, and the people generally are to be educated to regard the malady in the grave light in which it is medically held, and to take in consequence adequate means for its repression. A close supervision over individuals suffering from the disease in crowded localities and workshops is to be maintained. The medical members of the department regard it as quite feasible, even in face of the present estimate of 20,000 tuberculous citizens in New York, to restrict tuberculosis within the narrowest bounds, and eventually perhaps almost to exterminate it. Future comparative records from New York will prove to be of interest in this connexion. To our way of thinking the whole scheme is Utopian.

THE PHYSIQUE OF THE ARMY.

WE are very glad to see that the question of the physique and stamina of the officers and men of our Army is attracting attention. It is a subject of great and growing importance to which we have from time to time referred in the columns of THE LANCET for some years past. We are living in an age when the strain on physical and moral qualities, of which competitive examinations take little or no account, is often very considerable. Manliness, vigorous health, physical activity, and complete integrity of the sense organs in themselves count for a great deal in the officers of our Army, and they are usually accompanied by coolness of judgment, a dogged indifference to danger, and powers of endurance—the very qualities on which officers and men have had very frequently to rely of late in India and Africa. A competitive examination, we have always held, should be competitive all round, and the possessor of these physical qualities or of any physical superiority should, in the interest of the State and the Army, reap some advantage from them. They enable an officer to endure fatigue, help him to resist disease, and inspire trust and confidence in the men he has to lead, and these are the very qualities that eminently fit a man for the military service. It is notorious, of course, that great mental and physical activity are often combined in men of relatively small stature; but these, if strong, healthy, and well proportioned, need not—and, indeed, could not, considering the numbers they represent—be excluded from competing for the military services. As it is at present, however, we are excluding a number of most desirable candidates because they mature mentally very slowly and are not bookworms or have not those studious habits which are very distasteful at the ages at which candidates are taken for the Army and Navy. The Board of Visitors to Woolwich and Sandhurst in their last reports very wisely, in our opinion, express a hope that the military authorities will seriously consider whether it be not possible to introduce into the examinations into and out of both the Royal Military Academy and the Royal Military College a test for the physical capacity of the candidates. Although most people are agreed on the principle, it is when we come to apply it to practice that difficulties arise. And it is in this respect that we may call attention to a communication in the *Times* of the 8th inst. for some practical suggestions as to how the regulations for admission into these institutions might with advantage be amended with the view of securing this end.

THE NEW CHAIRMAN OF THE LONDON COUNTY COUNCIL.

WE congratulate Dr. W. J. Collins on attaining to the honourable position of Chairman of the London County Council, the most important municipal post, after that of Lord Mayor of London, in the world. The work of the London County Council in relation to medical and hygienic matters has been above reproach, so that we record with particular pleasure the election of a medical man to preside over its deliberations for a time. Of Dr. Collins's great abilities no one who has come into contact with him can have any doubt, while we believe that he will also display judicial impartiality and official dignity in the discharge of his new and onerous duties. With our congratulations to Dr Collins on his election we should like to couple a word of thanks to his predecessor. Sir Arthur Arnold was an excellent chairman from every point of view, and carries with him into the comparative privacy of ordinary membership of the Council the well-earned respect of the citizens of London.

THE VAGARIES OF VISION.

ON Friday evening, March 5th, Mr. Shelford Bidwell delivered before the Royal Institution a lecture on some curiosities of vision, and performed a number of experiments to illustrate the phenomena known as persistence and recurrence of vision. Perhaps the most interesting part of the lecture was that in which the lecturer attempted to throw some light upon a curious little optical toy which was brought before the public about a year ago, consisting of a number of discs of cardboard having black lines drawn upon them in such a manner that when the discs were rotated the black lines would appear as continuous bands, which bands appeared to the eye to be coloured, the tint varying according to the rate of rotation. The lecturer referred to some simple experiments which he had made in which black lines were made to appear as red. If a piece of brown paper is taken, a hole cut in it about half an inch square, and a pin fastened across the opening midway between and parallel with two sides with some stamp paper, and the whole moved backwards and forwards before a lamp, the pin will appear to have a border of red. Again, in the case of a printed book if placed before the eyes and alternately screened and exposed, either with the hand or a piece of cardboard, the black lines will appear for about a second to be of a red colour, the experiments showing that whenever a bright image falls upon the retina after short period of darkness the image appears with a coloured border which, under ordinary conditions, is of a red colour. The optical toy referred to is constructed on the principle of alternate periods of light and darkness, and whatever may be the cause of the red colour appearing in Mr. Shelford Bidwell's experiments it is probable that it bears some near relation to the varying bands of colour on the rotating discs. It is not everyone who will be able to see these effects upon a first

Hosted by Google

experiment, because the sensitiveness of the eye to colour is sometimes very feeble, but in almost all cases sensitiveness can be strengthened by practice. In the study of optical effects, too, the fact cannot too often be emphasised that we must know exactly what to look for and also the right spot to which the attention should be directed. We believe that an instrument called the "Chromoscope" which has been designed to show the effects referred to, can be purchased from Messrs. George Philip and Son of Fleet-street.

THE TWELFTH INTERNATIONAL CONGRESS OF MEDICINE.

THE committee in charge of the organisation of the Section of General Pathology and Pathological Anatomy desire to receive as quickly as possible the titles of any communications which our readers may be intending to send to the International Congress at Moscow, as well as brief abstracts of the principal conclusions to be drawn from the papers. The following questions have been suggested by the committee for discussion, and views upon them will be submitted by the scientific authorities whose names are severally appended: The Botanic Specificity of Pathogenic Microbes (Professor Hueppe of Prague), the Pathology of Thrombosis (Professor Cornil and Dr. Marie of Paris), the Origins of Different Forms of Diabetes (Professor Lépine of Lyons and Professor Minkowsky of Strasburg), the Pathology of Myxœdema (Professor Brissaud of Paris, Professor Ewald of Berlin, and M. Gley of Paris), the *Rôle* of Antitoxins in the Production of Artificial Immunity (Professor Behring of Berlin and Professor Bouchard of Paris), the Pathology of Inflammation and the Parts Played by Bloodvessels and Parenchyma (Professor Stricker of Vienna and Professor Klemensiewicz of Gratz). All correspondence with regard to the section should be addressed to M. G. Dourdoufi, Pretschistinsky boulevard, Jerusalmskoe Podvorie, Moscow.

THE PROPOSED LEGISLATION FOR HABITUAL DRUNKARDS.

IT is sincerely to be hoped that the Government will be able to carry out during the current session their intention of amending the laws relating to the treatment of habitual drunkards. Among members of the medical profession there is little, if any, important difference of opinion upon this subject. The necessity for some system of restraint and tutelage is generally admitted, and if no particular method has up to the present time been actually employed this is assuredly not from the want of either will or occasion. In the meantime certain recognised plans of treatment are becoming discredited. The lunatic asylum and the dipsomaniac are frequently found to be mutually unsuitable, and this incompatibility is absolutely certain where the habit of drunkenness does not amount to lunacy in the strict sense. Nor is the common prison the proper place of seclusion for such persons. This part of the subject was recently discussed at a meeting of the Society for the Study of Inebriety, when Mr. J. J. Pitcairn, assistant surgeon to the Holloway and Newgate prisons, expressed himself strongly against the system of prison detention, and showed that in many cases the prison ward is for the drunkard virtually a form of hospital, while, on the other hand, the terms of incarceration assigned by law to such inmates are too short to ensure any practically curative effect. The same writer, nevertheless, gives utterance to a widespread impression that the prolonged detention of confirmed inebriates in specially adapted institutions would go far to remedy this diseased propensity. Side by side with this arrangement must go, of course, an arrangement for the transfer to other hands, for so long as may be necessary, of their domestic and business interests. The first part of this plan is certainly desirable if it can be carried out, and there is little doubt that private enterprise, guided, of course, by legal regulation, would prove equal to the task. Whether it is incumbent upon Governments themselves to make provision for the charitable maintenance of such institutions is another matter, and it is open to question whether such an obligation should be enforced. Herr Schlangenhausen regards the establishment of asylums for drunkards in Great Britain and Ireland as only a question of time;[1] but the ratepayer would probably remind him, if consulted, that it is also a question of money and a subject for discussion. Even this part of the ideal scheme may by degrees be brought within the circle of possible attainments, but its execution must largely depend for some time to come on the energy of private enterprise. The other part, which has to do with the transfer of responsibilities which can no longer be regularly exercised by the drunkard, entails no public burdens. Our views upon this subject were briefly stated in THE LANCET of Dec. 5th, 1896. The system of trusteeship there suggested conforms in its general purpose, though not necessarily in all details, to that of Curatel, which was fully explained in connexion with our reference to Herr Schlangenhausen's opinions. We believe that the true solution of the problem will be found when this principle of trusteeship is embodied in a simple and effective mode of legal procedure.

CEREBRAL SURGERY.

IN a recent paper by Professor Hitzig, an abstract of which appears in the *Neurologisches Centralblatt*, an account is given of four cases of tumour of the brain in reference especially to the non-success of operation. The first case was that of a man, aged thirty-four years, who had received a blow from a hammer eight years before he came under observation. He had weakness and convulsive movements in the right arm and, later, weakness of the right leg and headache, but no sickness or optic neuritis. He was thought to have a cortical tumour, but none was found at the operation, although there was evidence of increased intra-cranial pressure. Three weeks later there were papillitis and sickness and convulsive movements of both legs. He rapidly passed into an unconscious condition and died. A large sarcoma was found apparently commencing in the centrum ovale, thence spreading into the cortex and also the corpus callosum. The second case was that of a woman, twenty-three years of age, who had vomiting, giddiness, gradual failure of vision in the right eye and also in the left. There was internal strabismus first on the left and later on the right side. There were optic neuritis and slight spastic paralysis of the left extremities and weakness of the right side of the face. It was supposed that there was a tumour in the cerebellum, but an operation did not confirm this. The patient afterwards died, and at the necropsy a large cystic glioma was found in the right frontal lobe which had flattened out the optic nerves, the third, the sixth, and the fifth nerves, and had compressed the right half of the pons. The third case was that of another woman, thirty-four years of age, who had attacks affecting the right arm beginning in the fingers and slightly affecting the head and the leg without loss of consciousness. There was rather laboured speech and slight right-sided weakness in the arm. Operation failed to reveal any tumour, and three years later her condition remained unchanged. The fourth case was that of a man who three years before had had an injury to the right side of the head, and who suffered from giddiness and increasingly severe headache, with subsequent right-sided paresis. This became permanent, and there were also right-side Jacksonian attacks commencing in the foot. There was tenderness on the left

[1] Vide THE LANCET, Dec. 19th, 1896.

Hosted by Google

side of the head, and at the operation a large endothelioma was removed. This apparently grew from the dura mater, and covered a large area of the convexity of the hemisphere and compressed the central region and the gyrus fornicatus. Death followed from shock.

ROYAL BOTANIC SOCIETY OF LONDON.

AT a meeting of this society held on March 6th Mr. John Birkett, F.L.S., in the chair, the Duke of Bedford, Sir G. Hamond Græme, Bart., and nineteen others were elected Fellows. A paper was read by Mr. Martindale calling attention to the great desirability of establishing in London an institution for the purpose of teaching botany similar to those in existence on the Continent, and proposing that the Council should take charge of the scheme and utilise a portion of their ground for the erection of the necessary buildings. From its central position and the fact of all the requisite material for study being at hand in a living condition, no other site in or near London would be so suitable for the purpose. The great fault of the present system of botanical teaching in England outside the medical schools and universities was that too much attention was given to botany solely with the object of enabling students to pass examinations, while economic and physiological botany was scarcely touched upon. If a young German were desirous of emigrating, previously to doing so he could attend a short course at one of the institutions at home and learn all that would be of most use to him about the grasses, fruits, and vegetable products of the country he proposed to settle in; but in England there was no such means of acquiring knowledge of this kind, and it was for the purpose of supplying such a deficiency that the establishment of the institute was proposed. Among those present who gave the scheme their hearty support were Professor Oliver of University College, Mr. D. H. Scott of Kew, Professor Henslow, Professor Greenish, Mr. M. Carteighe and Mr. E. M. Holmes of the Pharmaceutical Society.

A SUCCESSFUL SOCIETY!!

MR. STEPHEN COLERIDGE, on behalf of a so-called "anti-vivisection" society, has written to His Royal Highness the Prince of Wales concerning "hapless dumb animals" in London "*that daily and hourly are slowly cut up alive without even the pretence of anæsthetics.*" It is needless to say that any such proceeding is wholly illegal, and we are inclined to ask how it is that a society which has collected subscriptions from the public for many years past has not succeeded in convicting the criminals who are guilty of such atrocities. Mr. Coleridge is, we believe, a trained lawyer, and must know that "hearsay" is not evidence, and we hope that he would not venture to make such a statement to the Heir Apparent unless he believed he were prepared to justify not merely the general import but the letter of it. Mr. Coleridge appears to us to be on the horns of a dilemma. If he has knowledge of animals being "cut up alive without even the pretence of anæsthetics," he and his society are morally *particeps criminis* unless they make an attempt to obtain a conviction. If he has no such knowledge, he has attempted on inadequate ground to deprive the sick poor, whose welfare the Prince of Wales has so keenly at heart, of the stream of charity which is flowing towards them. But we take it that Mr. Coleridge has not succeeded in misleading anybody, and his amiable utterances will be regarded as merely due to poetic phrenzy gone sour. The anti-vivisection societies by their intemperate and exaggerated statements have gradually rendered the public immune to the poison which they are engaged in disseminating. They have never obtained a conviction for any offence against the Vivisection Act. They have not succeeded, happily, in arresting the legitimate pursuit of knowledge, and we venture to predict that this last utterance will have no influence whatever in lessening the contributions to the Prince of Wales's Fund. The Society for the Prevention of Cruelty to Animals can point with some pride to the successful crusade which it has forwarded. The anti-vivisection societies have had no solid success, and never can have any. One conviction would do more than millions of silly handbills and leaflets. The medical profession equally with the public would rejoice at the punishment of the perpetrators of the atrocities which Mr. Coleridge alleges take place daily and hourly. But until such conviction has been obtained we must continue in our belief that Mr. Coleridge's statement is absolutely devoid of any foundation whatever.

OPEN SPACES ABOUT BUILDINGS IN LONDON.

DR. J. F. J. SYKES, medical officer of health of St. Pancras parish, has presented to the vestry a valuable report on the powers and duties of the vestry in relation to the inspection of tenement houses, a term which, as defined in the existing by-laws of the vestry, denotes houses "let in lodgings or occupied by members of more than one family," and "'tenement' means any room or rooms in a tenement house let as a dwelling or lodging or for the use or occupation of a tenant." In commenting on the by-laws which direct that 400 cubic feet of air must be available for each person occupying a room "used both as a sleeping apartment and for some other purpose," while 300 cubic feet are deemed sufficient for each occupant of a room used exclusively as a sleeping apartment, Dr. Sykes recommends the adoption of a single minimum standard of cubic space, and suggests 400 cubic feet for all purposes, two children under ten years being reckoned as one adult. An addendum to this report deals with the subject of open spaces about buildings, and contains the disquieting statement "that there is a prospect that in course of time the whole of the open spaces about buildings may disappear." It seems that according to the London Building Act, 1894, in a new domestic building abutting upon an old street the open space to be provided to the building may be entirely covered in up to a level of sixteen feet above the adjoining pavement, and the consequence of this permission is that old houses possessing yards, areas, or open spaces in some form at the front or back, or both, are being rebuilt in such a manner that the whole of the previously vacant area is covered with a structure having a height of two or three storeys. The by-laws and regulations of the County Council and sanitary authorities are devised so as to cause drainage to be excluded from or placed outside of domestic buildings, but they seem to be rendered useless by a Building Act which enables a domestic building to embrace the whole of the drainage of the premises within its external walls.

TAKA-DIASTASE IN DYSPEPSIA AND GOUT.

TAKA-DIASTASE is an inodorous brown powder which acts energetically on starch, digesting it and converting it into sugar. Its discovery was the result of a lengthy investigation undertaken by a Japanese chemist named Takamine, who, while engaged in laboratory work in Glasgow under Professor Mills, F.R.S., was led to study the phenomena of malting, and subsequently continued his researches in Japan. In the result he found that a fungus, Eurotium oryzæ, of the Aspergillus family, when grown upon common bran, has a remarkable power of producing diastase, which can be separated from the bran by washing and percolation. A full account of the nature and properties of the new substance has already appeared in our columns.[1] Diastase

[1] THE LANCET, May 25th, 1895, p. 1332.

Hosted by Google

exists in ordinary malt, and effects the transformation of the starch of the grain into sugar, which is the first stage in the production of alcohol. In the animal economy the digestion of starch is accomplished by means of a special principle contained in the saliva, and when the natural secretion is either insufficient in quantity or inactive, giving rise to certain forms of dyspepsia, the deficiency may to some extent be remedied by the use of one or other of the numerous preparations of malt. Malt, however, is too saccharine for some gouty and dyspeptic patients, and for them Mr. Armstrong of Buxton, writing in the *Liverpool Medico-Chirurgical Journal*, recommends taka-diastase in doses of from three to five grains, given in powder with or immediately after meals. He has used it with excellent results in a considerable number of cases, both of amylaceous dyspepsia and of the form of gout which seems to be associated with that condition. He finds that flatulency and acidity are greatly diminished, that there is less strain on the intestinal digestion, that the gouty symptoms are much relieved, and that not the slightest discomfort, loss of appetite, or digestive disturbance is ever produced in consequence of the treatment.

THE INSPECTION OF MEAT AND MILK IN CANADA AND THE UNITED STATES OF AMERICA.

THE Provincial Board of Health of Ontario has issued, through Messrs. Warwick Brothers and Rutter, of Front-street, Toronto, a pamphlet giving a variety of information useful to those who are interested in the quality of our meat-supply. The importance which the question has for this country sufficiently appears from the fact that during nine months of 1896 we imported 436,223 cattle, of which the United States sent 308,159, and Canada 71,670; while the bacon from the United States during the same nine months amounted to 207,000,000 pounds. In 1896 the Legislature of Ontario passed an "Act for the Inspection of Meat and Milk Supplies in Cities and Towns," empowering municipal councils to establish public slaughter-houses and authorising local boards of health to take measures for ascertaining the purity of public milk-supplies and the general health of the cows; local boards are further authorised to provide for the testing of every such cow with tuberculin by a veterinary surgeon. Councils or boards availing themselves of the powers conferred by the Act are required by it to conform to the regulations in that behalf from time to time adopted by the Provincial Board of Health, and with a view to encouraging the introduction of meat and milk inspection the Provincial Board has now published a description of a slaughter-house suitable for a town population of 5000 persons, together with a plan, an elevation, and an estimate of cost. In the testing of cows with tuberculin "a 10 per cent. solution of normal tuberculin is to be injected to the amount of from one to four cubic centimetres according to age of animal..... The temperature must thereafter be taken regularly every three hours for a period of from twelve to fifteen hours..... Any notable rise of temperature indicates the existence of tuberculosis." Cows that give the tuberculin reaction, if they are wasting and show clinical signs of lung disease, shall be destroyed and the carcasses safely disposed of; but if they are in fair condition they may be either fattened as speedily as possible for slaughter, or their milk, after boiling for half an hour, may be given to pigs or calves. The pamphlet concludes with a description of the inspection of meat at Buffalo in the United States, and is signed by Dr. P. H. Bryce, Secretary to the Provincial Board of Health of Ontario.

THE public meeting to promote the National Jenner Memorial is fixed for March 31st. The chair will be taken by the Duke of Westminster.

THE festival dinner of the Irish Schools' and Graduates' Association will take place at the Café Monico on Wednesday, March 17th, Dr. Alexander Macalister, F.R.S., occupying the chair. The guest of the evening will be Lord Lister, P.R.S., and amongst those present will be Sir John Gorst, Sir Algernon West, K.C.B., Professor Jebb, M.P., Mr. Marcus Stone, Sir Ambrose Shea, and Professor Clifford Allbutt.

WE regret to announce the death on the 10th inst. of Dr. George Bretherton Barron of Southport. Dr. Barron, who was a member of the Council of the British Medical Association, was an admirably typical example of the general practitioner of this country, and we hope to be able to publish a record of his life and work in a future issue.

THE Medico-Psychological Association have appointed May 3rd for the next examination for their certificate in nursing and attending on the insane. April 5th will be the last day upon which candidates can enter their names. Schedules may be obtained from the registrar, Dr. Spence, Burntwood Asylum, near Lichfield.

THE Festival Dinner of the National Hospital for the Paralysed and Epileptic (Albany Memorial) will be held in the Whitehall Rooms of the Hôtel Métropole on Friday, April 2nd, when H.R.H. the Duke of Connaught, K.G., will preside.

DR. G. H. DARWIN of West Didsbury, Manchester, has been selected for admission as a Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England.

PROFESSOR CHARLES KELLY, M.D. Lond., has resigned the Chair of Hygiene in King's College, London, after a tenure of office of eighteen years.

LITERARY INTELLIGENCE.—The Rebman Publishing Company, Limited, announce that owing to a fire at their binders a large consignment of the "American Year-Book of Medicine and Surgery," issue of 1897, edited by Dr. George M. Gould, has been completely destroyed, in consequence of which they regret that they will be unable to deliver subscribers' copies for about three weeks.

PRESENTATIONS TO MEDICAL MEN.—Mr. Duncan Fletcher, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been presented by his friends, on leaving the Isle of Man, where for fifteen months he was a medical officer at the union Mills lunatic asylum, with a silver-mounted Tantalus, containing cut-glass spirit decanters. — Mr. A. McLeod Ross, M.B., C.M. Edin., F.R.C.S. Eng., of Aigburth-road, Liverpool, has been the recipient from members of the Brunswick Class, No. 3, of the St. John Ambulance Association, of a handsome double set of carvers in a case, in appreciation of his instructive lectures to the class. — The members of Court Prosperity, 1762, Ancient Order of Foresters, Nottingham, have presented Mr. Joseph Thompson, L.R.C.P. Lond., M.R.C.S. Eng., who has been associated with the court for upwards of twenty-five years as medical officer, and who is now relinquishing that post, with a valuable sterling silver salver, beautifully engraved, with an appropriate inscription of the presentation.—Dr. Alfred M. Saunders, on the eve of his leaving Downby, Orkney, was entertained at dinner on the 18th ult. by a number of friends at the Smithfield Inn and presented with a large marble clock and, for Mrs. Saunders, a silver cake-basket, as testimonials of their social gifts and the professional ability and courtesy shown by him during the seven years he had resided at Downby.—Mr. R. T. Cæsar, jun., L.R.C.P. Lond., M.R.C.S. Eng., of Maidstone, has been the recipient of a handsome oak stationery case from the boys attending the ambulance instruction in connexion with Sir Charles Booth's Trust continuation classes, as a token of appreciation of the course of ambulance lectures he had given them.

The Lancet Special Commission ON THE METROPOLITAN WATER-SUPPLY.

IV.[1]

THE LAMBETH WATERWORKS COMPANY.

History.

THE early history of the Lambeth Waterworks Company shows how very rapidly an excellent business was built up by a number of men who gave their time and energy to a work which supplied a very obvious want.

The first meeting of the original founders of the Company was held in April, 1785. A list had been prepared of the owners of over 600 houses who wished to be immediately supplied with water. Another list was handed in of the occupiers of another 600 houses, who, it was believed, would be glad to have water as soon as they saw what a convenience it was to their neighbours. At the same meeting an estimate as to the probable cost of the undertaking was submitted, and it was calculated that a profit of 12 per cent. and upwards could easily be paid; but it was decided that the projectors should not flatter themselves with an immediate advantage from the work to the extent that their own calculations seemed to hold out. It was resolved that this was not a visionary scheme, but a "business suggested and taken into consideration on substantial grounds by men capable of judging both of the expense and effect." A subscription list was opened, and it was decided at once to apply for an Act of Parliament. Mr. White, a clerk to the House of Commons, seems to have been the Company's Parliamentary agent. Sir Joseph Mawbey, one of the members for Surrey, and the Rector of Lambeth helped to draw up the petition, which was signed by those of the inhabitants who wished to be supplied with water. An Act incorporating the Company was obtained and received the Royal Assent on July 9th, 1785, on which day the proprietors appointed to meet at 2 o'clock at the New Inn near Westminster Bridge, in accordance with the statutory directions of the Act of Parliament.

The work was rapidly taken in hand. Premises were obtained in Belvedere-road, near the site of the present Waterloo Bridge, which was not then built, and nearly opposite to Hungerford Market. A steam engine was put up, but it was not at first capable of supplying a higher service than 42 ft. above the Thames high-water mark. Wooden pipes were used for conveying the water. The proprietors showed great attention to the details of their business and printed and distributed handbills among the inhabitants of Lambeth to say that after the following Christmas they would be glad to supply anyone who lived within reasonable distance of their mains. Letters were also written to certain fire assurance companies asking them if they would like to take part in the expense necessary for keeping a fire engine ready to work. In this application the Company were not successful, but the request shows, it must be admitted, excellent business instincts.

At the end of the last century there is no doubt that a water-supply was urgently needed in Lambeth, and requests were sent to the Company asking them to extend their area of supply as quickly as possible. In 1790 some of the inhabitants of St. George's-fields wrote to say that unless they were speedily supplied with water they would have to leave their houses, as no lodgers would remain with them if they could not get a supply. The work of development proceeded so rapidly that in 1791 the clerk reported that they could not obtain small pipes as quickly as they wanted them. In 1800 some of Watts's improvements were adopted for working the engine which was then in use.

The early records of the Company contain instances of people who clandestinely laid on the water to their houses from the Company's mains. In such cases the Company acted with great vigour. Thus, in the case of one Mr. Green, who supplied his neighbours from his own tub, it was decided "that the ferril that serves the house be drawn, and that the water be not laid on again until the several houses reported to have been supplied laid down separate pipes." The Company's Act enabled them to impose a penalty of from £50 to £1 a day for stealing water. One man who was caught doing this was called to a meeting of the Board and informed of the penalty to which he had rendered himself liable. He pleaded that if it were imposed it would "materially injure his circumstances, and that he had a family of six children." The matter was settled by the culprit paying the arrears of water rent and giving £5 to a charity. In another case the directors agreed to give an informer half of any sum which might be obtained from an individual who had taken the water without paying for it.

The Company gradually extended their area, and in 1802 it was decided to go as far as The Horns, Kennington, that an ample supply might be given to "that respectable and populous neighbourhood." In the same year it was decided that a certain number of 10-in. iron pipes should be laid every year, provided that the outlay did not interfere with the dividends; and in 1816 it was decided to use only iron mains from that date. In the year 1805 a new 24-horse power engine was erected and a fixed instrument called a "dolphin" was put over the mouth of the suction pipe which conveyed water from the river. The dolphin took the place of a floating rhomboidal fender which had previously been used. The Company did not remain entirely without rivals. In 1805 the South London Waterworks were established. At first the relations between the Companies were friendly, and two years after their formation the Lambeth Company offered to supply some water which their rivals were unable to do in consequence of the destruction of their engine by fire. A few years later, however, there was a fierce competition between the Companies and this raged for some years.

After the building of Waterloo Bridge many new streets were made in a southerly direction, and the Company at once put an iron main in the direction of the Obelisk, St. George's-fields. From the first the financial arrangements of the Company seem to have been made with a view to the development of a big business, and money which might have been paid in dividends was used for paying the expenses incurred in extending the area of supply. In 1819 a resolution was passed by a committee of the proprietors that it would be disastrous if it should happen from the "impatience of some proprietors" that they should be induced to break through their rule of extending the business and draw money out of the concern; it would either "shackle" their proceedings or compel them to get into debt. In that case the committee thought that the sun of their prosperity would very soon set.

The proprietors took a keen interest in the reputation of the water they supplied, and in 1824 the solicitors of the Company threatened one Mr. Keys, a plumber, for his interfering with their customers "by defaming their commodity." On the other hand, Mr. Mathews, who wrote in praise of Thames water, was rewarded by receiving the sum of five guineas.

In the year 1831 it was decided to buy some land on high ground and to make a "filtering apparatus," and some land was bought on Streatham-hill—the site of the present reservoir. Two years later the ground on which the present Brixton pumping station is situated was bought, and it was decided to lay down an iron main from the works to the new reservoir which had been made at Brixton. An Act of Parliament was obtained in 1834 and the share capital of the Company was increased to £143,800. Up to that time the proprietors' capital had been limited to thirty-two shares of £150 each.

The outlying districts south of the Thames which were not supplied by the Company obtained their water with difficulty. The poorest people were supplied from water-carts and had to pay from ½*d*. to 2*d*. a pail for it. A great many petitions were sent to the Company to ask them to extend their supply. Complaints as to the insufficiency of the water-supply came from districts as far apart as Kingston and Beckenham, and the Company resolved to extend their business, to abandon their original works, and to remove their intake higher up the river. This decision was come to in 1847 and the Company were re-incorporated in 1848, and the Act authorised the construction of works at Seething Wells, Ditton, and gave them power to extend the area of their supply. The works at Ditton were opened in 1852, and the directors justly prided themselves on being the first company which resolved

to obtain their supply from a less impure source by going higher up the river. In 1852 the other Metropolitan Water Companies which took their water from the Thames were compelled by an Act of Parliament to move their intakes to some point above the tidal portion of the Thames. At this time the Lambeth Company had already done this, a fact which must always be remembered to their credit.

In 1871 the Company decided to remove their intake from Seething Wells still higher, because the water at Seething Wells was discoloured and turbid whenever the rivers Mole and Emmett were in flood. An Act to enable the Company to move to West Molesey was obtained, and subsiding reservoirs and pumps were erected there and the works completed in 1874. During the progress of the excavations at West Molesey it was discovered that there was a quantity of water in the gravel, and this was used as an additional source of supply. The dates of the Lambeth Water Company's Acts, besides those above mentioned, are 1848, 1856, 1869, 1871, 1883, and 1886.

Present State: General Description.

The Lambeth Waterworks Company supply Molesey, Ditton, part of Wimbledon, Balham, Brixton, Streatham, Lambeth, Walworth, Dulwich, and Sydenham.

The sources of supply are: (1) the Thames at West Molesey; (2) gravel beds near the Thames at Molesey; and (3) the Thames at Ditton (in cases of emergency).

The stations of the Company indicated upon the map are eight in number: A, Molesey (intake, reservoirs, pumping station); B, Ditton (reservoirs, filter beds, pumping station); C, Coombe (reservoir); D, Brixton-hill (reservoirs, pumping station—see Fig. 1); E, Streatham (reservoir—see Fig. 2); F, Norwood (reservoir); G, Selhurst (reservoir—see Fig. 3); and H, Rock-hill, Sydenham (reservoir—see Fig. 4).

Molesey.—The chief intake of the Company is from the Thames at West Molesey, on the south bank of the river. The area of the property here is rather over thirty-six acres, and the works consist of the intake, a pumping-station, an arrangement for obtaining water from the gravel beds, two reservoirs, and three cottages, one containing a small board-room.

Intake.—There are five inlets from the Thames, and they are placed close together. They are guarded by an outside grating composed of bars an inch in width, with spaces of one inch between each bar. A screen with smaller meshes is situated inside. There are grooves for two sets of screens, but only one set is used at a time. The inner screens are of galvanised iron, with ⅜ in. meshes. The inlets allow the water to pass into a brick culvert, which passes under the towing-path to the engine-house well through a sluice-house.

Pumping arrangements.—The river water is pumped up a height of about 14 ft. to the reservoir. This is done by a pair of centrifugal pumps, worked by two horizontal engines, and capable of raising 25,000,000 gallons of water daily. There are also two vertical engines of 50 horse power each, which are capable of pumping 17,625,600 gallons of water daily. These engines are used for pumping into the subsiding reservoirs and culvert and for pumping water from the gravel beds. When visited on Jan. 6th some of this machinery was being overhauled and repaired.

Water from the gravel beds.—A considerable quantity of water is obtained from the gravel beds situated on the property at Molesey. This water is collected by perforated pipes, which are laid in the ballast above the clay at a level of about 7 ft. below the summer water level of the Thames. Perforated earthenware pipes are arranged in a double line all along the northern side of the property near the towing-path, parallel with the river, and for some little distance near the eastern boundary of the property, at right-angles to the line just described. The pipes vary in size from 12 to 24 inches. There is a line of 12 in. pipes 771 ft in length, a line the same length of 18-in. pipes, a line of 200 ft. of 24-in. pipes, and a line 459 ft. in length of 18-in. pipes. The water collected by these pipes passes into a tank 12 ft. in depth and 5 ft. in diameter; from this tank it flows into an engine-house well, from which it is pumped into the reservoirs. The amount of water which can be obtained from the gravel beds is rated to be 6,000,000 or 7,000,000 gallons daily.

Reservoirs.—There are two reservoirs situated on the side of the engine house remote from the Thames. The reservoirs occupy an area of thirty acres and are capable of storing 128,000,000 gallons of water. The lower part of the sides of the reservoirs is concreted and the upper part is paved with bricks. For the supply of Ditton the upper part of the water is drawn off. The arrangement for conveying water to the filtration works at Ditton is that the iron pipes which take the water to the culvert from the reservoirs are fixed to floating buoys, thus ensuring that the "top water" only is drawn off. No water is filtered at Molesey—it all flows by gravitation to the station at Ditton.

The water is conveyed to Ditton by two separate channels; (1) an iron main 36 in. in diameter; and (2) a culvert. For the greater part of the distance the water passes in an oval brick culvert of which the dimensions are 5 ft. 9 in. by 4 ft. 9 in. In two places the brick conduit is replaced by a 54-in. iron pipe. The two places in which iron pipes are used are (1) near and under the rivers Mole and Ember for a distance of 800 yards; (2) through the village of Thames Ditton for a distance of 550 yards. The culvert is of older date than the 36-in. iron main.

Seething Wells, Ditton.—At Seething Wells the whole of the water-supply of the Company was formerly taken from the Thames. Water can, in cases of emergency, be taken at this point, as the old intake arrangements remain. The engineer of the Company states that it has not been necessary to use them for two years, and that they have not been used during that time. The station consists of two parts, divided by the Portsmouth-road. The older part, that next the river, contains four filter beds and a small reservoir. The total area of these filter beds is between three and four acres. On Jan. 6th it chanced that one of the filter beds was being re-made. As the construction of this filter differs from that of those usually made at the present time it may be worth while to describe it briefly. The bed of the filter is formed by thick, open-jointed slates supported on brick walls. The chamber below the slates is about 4 ft. in depth. Above the slates a layer of large gravel is placed, then a layer of shells, and then, at the top, the usual layer of fine sand. The newer part of the station is situated to the south of the Portsmouth-road, and consists of the pumping station, reservoir, and filter beds. There are eight filter beds, and these are placed 30 ft. higher than the four older ones next the river. More than half the water, therefore, has to be pumped up to them, and this is done by means of two compound beam engines of 100-horse power each.

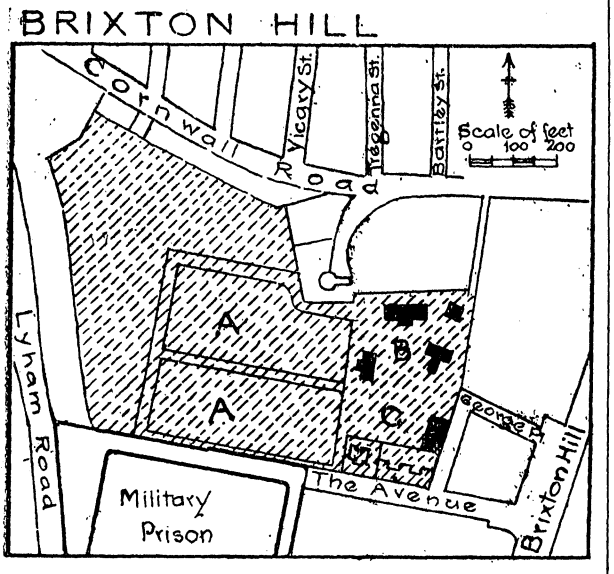
Filter beds.—The eight newer filter beds have a total area of about nine acres. The filtered water is collected into tanks. Each filter has a separate tank of its own, so that the water from any filter bed can be examined separately. All these tanks are connected with one main.

Engines.—From Seething Wells the filtered water is pumped to Coombe and Brixton. The engines used for pumping to Brixton are four compound beam engines of 180-horse power each, three compound beam engines of 150-horse power each, one compound beam engine of 150-horse power (all of the Woolf type), and one Worthington triple expansion engine of 420 horse power. For the supply of Coombe reservoir a compound beam engine of the Woolf type, 150-horse power is used to work a double-acting solid plunger pump. Steam for working the engines is generated by Cornish and Lancashire boilers, which supply two steam mains. All the boilers of 100 lb. pressure can thus be connected through one main, and those of 50 lb. pressure through the other. The coal-supply is landed from the Thames at the old part of the station and goes in trucks through a tunnel under the Portsmouth-road to the coal stores in the new part of the station.

Coombe reservoir.—The reservoir at Coombe Warren is built on land belonging to the Duke of Cambridge, 180 ft. above ordnance datum. It is situated not very far from the shooting-range just off the high road from Portsmouth to London. The reservoir is built on brick arches and is capable of holding 1,150 000 gallons of water. At Coombe there is a stand-pipe 50 ft. in height and 220 ft. above ordnance datum. The water for the supply of Surbiton, Kingston, Esher, Ditton, and East and West Molesey comes from this reservoir.

Brixton hill.—This station is situated at Brixton-hill (see Fig 1), just to the west of the thoroughfare of that name. The area of the works is about twelve acres, and the height above ordnance datum is 115 ft. The office of the Company, two reservoirs (Fig. 1, A A), a pumping station (Fig. 1, B), workshops (Fig. 1, C), and four cottages are situated here.

Reservoirs.—There are two reservoirs built on brick arches, and each is capable of holding 6,000,000 gallons of water.



Hosted by Google

The mains which bring the water from Ditton come up into the space between them.

Distribution of water.—From Brixton-hill the town district is supplied by gravitation, the water being distributed by four main trunks—24, 20, 18, and 12 in. in diameter respectively. For the supply of the country districts the water is pumped from Brixton to Streatham, Selhurst, Norwood, and Rock-hill reservoirs.

Engines.—There is a compound Worthington pump of 125-horse power which is used for pumping water to Streatham. This engine is worked by three Cornish boilers. A compound beam engine, 120-horse power, working two bucket and plunger pumps, is used for pumping to Rock-hill

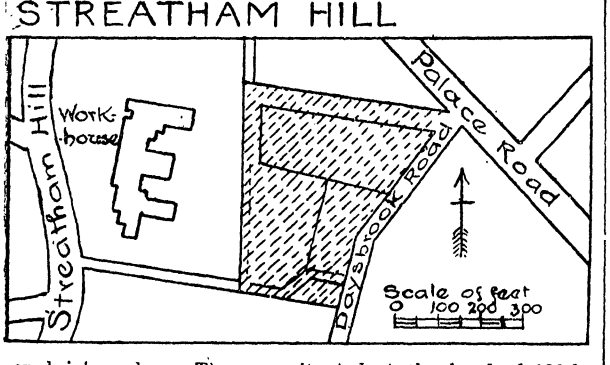


FIG. 1.

reservoir, and works under 320 ft. head of water. Three compound beam engines of the Wolff type, each 60-horse power, work bucket and plunger pumps and are used for pumping water to Streatham and Selhurst. The steam is generated by eight Cornish boilers. A compound beam engine of 130-horse power, working a bucket and plunger pump, and another engine of 160-horse power pump water to Norwood. There is a 120-horse power compound beam engine of the Macnaught type working a bucket and plunger pump and another of 140-horse power of the same type. The former of these is used when occasion requires for pumping to Rock-hill, Norwood, Selhurst, and Streatham. The latter is used for pumping to Norwood, Selhurst, and Streatham. There is also a small compound beam engine of 30-horse power which can be used for pumping to Rock-hill.

Streatham-hill.—Streatham-hill station (see Fig. 2) has an area of four acres. It contains two covered reservoirs built

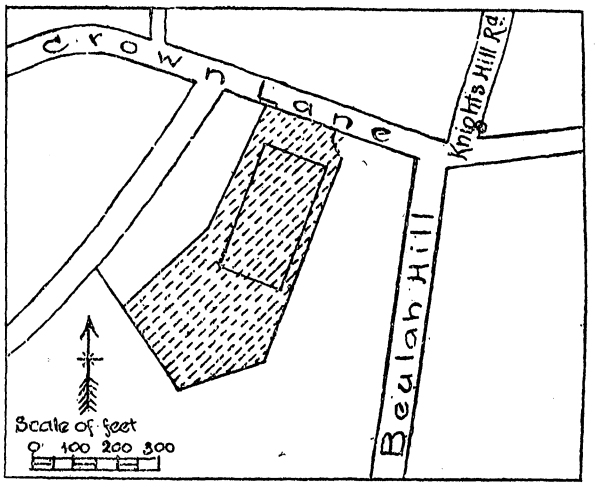

FIG. 2.

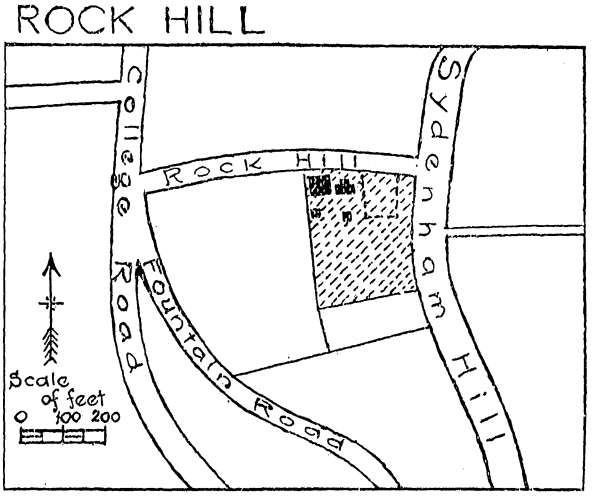
on brick arches. They are situated at the level of 198 ft. above ordnance datum. Each reservoir is capable of holding 3,750,000 gallons of water. The reservoirs are covered with earth and turfed at the top.

Norwood reservoir.—This station is situated in Crown-lane, Streatham. (See Fig. 3). The reservoir like all the others is built on brick arches and occupies an area of about one acre. It has a capacity of 5,000,000 gallons. The reservoir is

FIG. 3.



Norwood Reservoir.

covered with earth and turfed over. There is at this station sufficient area of spare ground to build another reservoir the same size. A caretaker's cottage is situated here.

Selhurst reservoir. — The Selhurst station is situated near Thornton Heath. The reservoir is 218 ft. above ordnance datum. It is built on brick arches and has a capacity of 2,500,000 gallons. The reservoir is covered by about 3 ft. of earth and turfed over. In the description of this station that was given to the last Royal Commission on the Metropolitan Water Supply it was said that there was a stand-pipe. Now, a stand-pipe is said to be "a curved vertical pipe arranged as a part of the main in waterworks to give the necessary head to supply elevated points," &c. There is no such "curved vertical pipe" at Selhurst, but there is an arrangement which acts as a stand-pipe. An 18-in. pipe is laid in the public road up the hill at a level of 42 ft. above that of the reservoir. When the water is pumped into this pipe an increased pressure is put on the district main. So the effect is the same as if there were a stand-pipe 42 ft. in height.

Rock-hill reservoir is on the brow of Sydenham-hill and is close to the Crystal Palace. (See Fig. 4.) The area here

FIG. 4.

occupied is one and a half acres. The reservoir is built of brick arches and is capable of holding 500,000 gallons of water, and is situated 372 ft. above ordnance datum. There is

Hosted by Google

also a high service tank 387 ft. above ordnance datum and capable of holding 115,000 gallons of water, and a stand-pipe 60 ft. in height. The top of the stand-pipe is 412 ft. above ordnance datum. During the day the water is pumped over the stand-pipe for high service and distributed in the neighbourhood. At night the water is pumped to fill the reservoir. The main is charged from the high-service tank.

Area of Supply.

The Act of 1848 authorises the Lambeth Waterworks Company to supply the places given in the following lists. Of these places some are entirely supplied, some partly supplied, some not supplied.

Supplied: Beckenham (the part of the parish lying on the western side of the River Ravensbourne), Esher, Kingston-upon-Thames, Long Ditton, Malden, Merton, Mitcham, Streatham, Thames Ditton, and Tooting Graveney.

Partly supplied: Battersea, Bermondsey, Camberwell, Christchurch, Clapham, Croydon, Lambeth, Lewisham (the part of the parish lying on the western side of the River Ravensbourne), Morden, St. Mary Newington, Newington Butts, Putney, St. George the Martyr, St. Saviour, Wandsworth, Wimbledon, and the Clink Liberty.

Not supplied: Horselydown, Rotherhithe, St. Olave, and St. Thomas.

The Act of 1871 authorises the supply of East Molesey and West Molesey, and these places are supplied by the Company.

The Lambeth Company supply about 150 houses in the parishes of Ham and Hook and about 200 houses in the parishes of Cheam, Chessington, Cuddington, and Ewell, which are outside the limits of the special Acts of 1848 and 1871.

Table of Statistical Details given by the Lambeth Waterworks Company for the Year 1896.

SUPPLY.	Average daily supply in gallons	2,855,836
	Percentage delivered for other than domestic purposes, exclusive of waste	25%
	Number of houses supplied	105,448
	Number of houses on constant supply	67,215
	Estimated population supplied	738,136
RESERVOIRS.	Number	5
Subsiding and storage unfiltered water	Area in acres	31
	Available capacity in gallons	123,000,000
Storage filtered water reservoirs	Number	8
	Capacity in gallons	23,765,000
ENGINES.	Number	28
	Horse power	3,665
	Greatest lift	380 feet.
	Head of pressure in the district supplied	Greatest, 380 feet; least, 30 feet.
WATER-PIPES.	Total number of miles of water-pipes	738, of which 544 are constantly charged.
	Number of miles of water-pipes in the metropolis	442, of which 386 are constantly charged.
	Number of miles of streets with water-pipes constantly charged in the metropolis	242¾; many streets with two and three, and some with six, lines of pipes.
	Number of hydrants erected within the metropolis	3733 public hydrants, 471 hydrants for street watering, 182 private hydrants, and about 10,000 fire-plugs.
FILTERS.	Number of beds	12
	Area in acres	12½
	Depth of sand and other materials	7 feet.

THE King of Sweden has appointed Mr. P. Michelli, secretary of the Seamen's Hospital, Greenwich, to be a Knight (1st class) of the Order of the Wasa.

SANITATION AND THE PLAGUE PANIC AT MARSEILLES.

IF it were possible to establish a pillory where the names of the towns which have most sinned against the laws of public health might be exposed to public contumely, there can be little doubt that prominent among such offenders would stand the town of Marseilles. Blundering intrigue, deception, and ignorance seem to be the chief characteristics of the sanitary administration of that town. For instance, in 1884 there was a severe epidemic of cholera in the neighbouring town of Toulon. Marseilles was for taking all manner of measures against Toulon, but very great care was displayed to conceal the fact that the Toulon epidemic had in all probability come from Marseilles. While lengthy discussions were held as to the importation of cholera from the French colonies because there had been some cases on board a man-of-war which arrived at Toulon, the authorities at Marseilles carefully concealed the fact that there had been some months previously several deaths from cholera at one of their own hospitals. The sisters who had nursed the dying men were convoked and made to swear that they would keep the matter secret. Some years elapsed before the truth was generally known, and then, of course, this knowledge came too late to be of use. As for the filthy condition of Marseilles, this has been very fully described in these columns.[1] In a great number of houses there are overflow pipes from the cisterns which bring sewer air up to the surface of the drinking water supply. In many other houses there are no drains whatever. In 1893, during the cholera epidemic, there were some 14 000 houses at Marseilles that had no sanitary accommodation of any description and the inhabitants were obliged to throw out their night soil into the streets. The sea baths at Les Catalans were situated within a stone's throw of a large sewer outfall. Most of the other sewers fell into the old and tideless port, whence some 80,000 cubic metres of foul deposit are drenched out annually. The odour given off by the bubbles of gas that burst on the surface of the water in the port are extremely obnoxious; but it is not necessary to describe anew all these abominations. It was thought that Marseilles had recognised the error of its ways and had boldly entered upon an era of sanitary reform. In October, 1892, there was a slight epidemic of cholera, causing eighty-two deaths. The existence of this epidemic was officially recognised and all available measures were taken, apparently with success, to stamp out the disease. At the same time Marseilles won the honour of being the first town in France which obtained a special law, not only sanctioning a complete drainage scheme, but arming the authorities with extensive compulsory powers, so that the inhabitants should be forced to connect their houses with the new sewers and construct properly flushed and ventilated closets and drain pipes.[2] The scheme was exhibited by M. Cartier at the Universal Exhibition of 1889 and obtained the silver medal It formed the basis of a convention dated Aug. 21st, 1890, ratified by a vote of 29 out of 32 municipal councillors of Marseilles on the 4th of the following October. This scheme was sanctioned by a special law of Parliament, dated July 24th, 1891, and promulgated by the Presidential Decree of Aug. 27th, 1891.

The works were commenced on Oct. 8th, 1891. The sewers to be built were to measure in all 132,839 metres in length and the entire work was to be completed in five years—that is to say, on Oct. 8th, 1896. A penalty or fine of £20 for each day's delay was to be imposed if the contract was not executed at the appointed date; but hardly had the work begun then a systematic opposition was organised against its execution. As the law could not be altered attempts were made to create so many obstacles that the contractors themselves would be driven to demand the rescinding of their contract. As it was necessary to purchase land, notably for the installation of the pumping stations, it was easy to create delays by opposing legal quibbles to the compulsory expropriation of premises, &c. By taking special measures the contractors hoped to terminate the works in three instead of five years, which would have

[1] See THE LANCET, April 1st, 8th, 29th, and May 6th, 1893.

[2] For a full description of this scheme of drainage and map see THE LANCET, May 6th, 1893.

Hosted by Google

been a great benefit to the town and have placed it to-day in a position to defy the invasion of the plague. But these good intentions were defeated by the stubborn opposition of the adversaries of the scheme. In the interval a new municipality had been elected, and the majority of its members was antagonistic to the scheme of drainage in course of execution. Nevertheless, in April, 1896, 80,680 metres of large sewers and 96,900 of small pipe sewers were laid; there only remained 8800 metres to finish the contract. Of 933 automatic flush tanks 880 were in their places, and 2140 manholes out of a total of 2175 were completed. Out of 30,000 metres of old sewers which had to be repaired and adapted to the new system 27,900 metres had been so treated. Pumping stations with a force of 480 horse power were in working order. But while the construction of the sewers was thus pushed forward the town was morally and materially pledged to increase its water-supply so that the sewers and the house drains should be properly flushed. Nothing of the sort has been done.

The sewers are built and are ready, but the town is not ready. The municipality even refuses to accept the sewers and will not allow the houses to be connected with them. There is a fierce conflict between the local authorities and the Prefecture, which represents the Central Government. The latter is seeking to compel the municipality to execute its side of the contract. The law says that houses must connect within two years of the completion of the sewers. This connexion will cost from £40 to £50 per house, and more for large houses where several closets are required. We foretold when describing this scheme that as soon as the people of Marseilles understood better what this contract meant they would rebel against it. Fortunately the matter is in the hands of the Government, and not of the municipality. As we said when criticising the scheme four years ago: "No municipality could drain the town of Marseilles. The population is far too ignorant, and any municipality that attempted to put syphon-traps, flush-tanks, and, in fact, proper closets into the houses would be very soon turned out of office. Yet all this will now have to be done; but it is the Prefect, it is the Central Government of France, that will have to enforce the due execution of the contract signed. The Prefect is quite independent of the Marseilles elector, and as for the municipality which signed the contract it has long ago ceased to exist. The Marseilles population will be appalled when they see what sanitation means and what it costs, for we must remember that the majority of houses have no waterclosets at all, and that there is hardly such a thing in the whole town as a proper watercloset. Probably 90 per cent. of the population of Marseilles have never even seen a sanitary closet with a two-gallon flush, trap, ventilated four-inch soil pipe, &c., yet these things are to be provided in all the houses, and this in the brief space of two years after the completion of the sewers." These words, published in THE LANCET of May 6th, 1893, are now fully borne out by the attitude of the population and municipality of Marseilles. Doubtless, the Government will, in the long run, overcome this local resistance; but in the meanwhile precious time is being lost, and by maintaining Marseilles in its filthy condition thousands of lives are wilfully and uselessly sacrificed. The death-rate of Marseilles for an average of twenty years was estimated by Dr. Proust, in 1889, at 32 per 1000. In the Hotel de Ville district it was equal to 47·4 per 1000. With proper sanitation this death-rate could, to judge by what has been done in many other towns, be reduced by one-third. One out of every three deaths that occur in Marseilles might be prevented. The greater part of the new sewers of Marseilles, if, instead of opposition, every facility had been afforded, could have been built two years ago. By this time most of the houses might have drained into these sewers; many thousands of lives would thus have been saved, and there would remain no excuse, no justification whatsoever, for the present ridiculous panic which the fear of the plague has occasioned. But in 1893 the reaction against sanitary reform was master of the situation.

In February of that year another cholera epidemic broke out. There were 102 deaths, but this epidemic was not officially recognised. Disinfection cannot be enforced unless an epidemic is officially declared. Consequently, several persons refused to have their premises disinfected. Under such circumstances it is not surprising that the epidemic broke out again in May and continued till the autumn, causing, as was stated at the time at the Ministry of the Interior, 767 deaths, making a total of 869 deaths from cholera during 1893. The local authorities officially acknowledged the existence of cholera in 1892, when there were 82 deaths; they officially denied the existence of cholera in 1893, when there were 869 deaths from this same disease. Thus Marseilles totally disregarded the Dresden International Sanitary Convention to which the French Government had subscribed; though in 1892, under circumstances far less serious, they had observed its stipulations. Of course, this inconsistent policy was due to the fear that by again officially recognising the existence of cholera at Marseilles the shipping interests of that port would be affected. But what shall we think of the present attitude of the local authorities? Cholera is far more dangerous to Western Europe than plague. Recent experience has proved that we are not yet free from the danger of cholera; but though ships and travellers have come from plague-infected countries over and over again they have not imported plague in this part of the world. For weeks ships had arrived at Marseilles from Bombay, where plague existed in a virulent form, and no one took the slightest notice nor was any mischief done. But one day the papers announced that a small boat which was making its way up the Seine to Paris with some carpets from Bombay on board had been stopped. Thereupon an indescribable and inexplicable panic set in at Marseilles. That town, which had been so anxious that nothing should be done likely to interfere with its commercial relations, suddenly declared itself in favour of applying quarantines in the strictest possible manner. The measures taken exceeded considerably what the law sanctioned, but the authorities at Marseilles declared that if merchandise from India was landed there would be riots and bloodshed. So great was the determination shown that the Government had to yield and strict quarantines were imposed. The population which had failed to take proper precautions against the real danger of cholera enforced illegal and exaggerated precautions against the very problematical danger of plague. The memory of the terrible plague epidemic which devastated Marseilles in 1720 has not been obliterated and accounts for the actual panic. This terror has caused the present inconsistent action. In 1893 Marseilles acted illegally to prevent interference with its commercial interests, and to-day Marseilles has again acted illegally, with the result that it has completely wrecked those self-same commercial interests. The Central Government, on its side, by tolerating this illegal action so as to prevent bloodshed, has produced a state of affairs which may well provoke the bloodshed it seeks to avoid.

The imposition of quarantines has thrown the dock labourers out of employment. Further, the oil and soap mills are at a standstill. Marseilles is renowned for its soap, which is supposed to be made with the oil from the olives of the neighbourhood; but what will become of French olive oil without Indian linseed? The demand for the renowned olive oil of Provence is far and away in excess of the supply. The deficiency is made up by adulteration with linseed and cottonseed oil; and now that the importation of linseed from India is checked the oil and soap factories are discharging their workpeople. The town of Marseilles, having broken the French law and brought about this calamity, thereupon coolly applies to the French Government to send subsidies out of the public treasury to relieve the distress caused by its own illegal action. On Feb. 17th last there were threatening demonstrations of the unemployed in the streets of Marseilles. The police had to turn out in force and some rioting ensued. The Prefect had to appeal to the employers and beg them to reinstate some of the men they had discharged. The mayor, on his side, opened relief works at the Cemetery of St. Charles, which is to be cleared. In the Catalan district a yard was opened where men were set to work at sawing wood, and many other efforts were made to relieve the distress of the unemployed. Nevertheless, the penury is so widespread that several deaths from starvation have been recorded. Such are the blessings of quarantine! On the other hand, has the danger of importing plague, if such danger exists, been avoided? Hardly had the quarantine been imposed than it was discovered that there was no proper means of disinfecting the suspected ships. Dr. Chantemesse, of the Pasteur Institute, was dispatched in hot haste to the quarantine station of Frioul, an island outside the port of Marseilles. He was accompanied by members of the Special Commission recently appointed by the Sanitary Council of Marseilles. These gentlemen discussed how a chamber could be installed for the fumigation of such merchandise, &c., as could not

Hosted by Google

be placed within the disinfecting stoves and exposed to the action of steam under pressure. M. Guérard, engineer in chief of the *Ponts et Chaussées*, was instructed to draw up an estimate within the twenty-four hours. He reported that such an installation would cost £6000. Thereupon another conflict arose as to who should pay this sum. It was argued that as, even in normal times, the State receives £16,000 a year from the ships detained at Frioul, it was the Government and not the municipality that should pay.

While these matters are under discussion and the commerce of Marseilles is being very seriously injured it is evident that the quarantine has been broken through over and over again. If the plague can be imported by passengers and merchandise, any number of passengers and merchandise coming from Bombay were landed at Marseilles after the plague had begun and before the quarantine was imposed. Then during the two previous years plague might in a like manner have been imported from China, notably from Hong-Kong, for no one ever thought of taking any precautions. Now, again, that the quarantine has been imposed at Marseilles, what happens? Passengers to avoid this inconvenience change ships at Alexandria. There is no quarantine against Egypt, therefore passengers from Bombay by merely changing ships on their way homewards can land at Marseilles without let or hindrance. Others have landed at Brindisi and entered France *viâ* Modena. Indeed, it has been proved over and over again that, in face of modern facilities of communication, it is absolutely impossible to organise an effective quarantine. Sanitary improvements constitute the really effective check to the spread of epidemics. Such improvements have been attempted in Marseilles, but we have seen what obstacles are placed in the way of their realisation.

THE INTERNATIONAL SANITARY CONFERENCE.

FROM Venice under date March 6th our Special Correspondent writes:—

Its preparatory business concluded, the Conference nominated two sub-committees to formulate measures of defence against the invasion and spread of the pestis bubonica, one committee acting for Europe, the other for the non-European countries.

The European sub-committee proposed, with the approval of the Conference, that the countries in which a single case of the "pestis" had been certified should notify the same to the others, either through diplomatic or consular agencies, or, failing these, directly by telegraph. Thereafter detailed reports on the origin, course, and issue of the disease should be dispatched to the same countries at least once a week, the reports indicating specially the measures adopted to restrict as much as possible the spread of the "pestis."

For "infected arrivals by rail" or otherwise by land the sub-committee, again with the approval of the Conference, proposed to make disinfection severely obligatory. Land quarantine and sanitary cordons are to be suppressed, the delegates being unanimous in discrediting such measures and in replacing them by disinfection as practised by modern science. Each country, however, may reserve the right of barring its own frontiers, only, however, against *bonâ fide* cases or others warrantably suspected as such. When medical visits are established on a frontier these must, to save time, synchronise with the custom-house examinations. Passenger trains, with luggage or postal mails, shall not be detained at the frontier; but if a carriage be found to contain a real or suspected case of "pestis" it shall be unhooked from the train at the frontier or the nearest station, so as to be disinfected and shall join the train following, while the original train proceeds on its course.

Travellers coming from infected countries shall be subjected to a surveillance of eight days. Individual Governments may reserve the right of taking special measures of precaution against gipsies, vagrants, emigrants, or such persons as cross the frontier in companies.

For the disinfection of ships the following regulation was approved:—Patients suffering from the "pestis" to be immediately landed and isolated; the rest of those on shipboard to be subjected to surveillance not exceeding ten days, counting from the development of the last case; passengers' personal effects, luggage generally, and goods or cargo to be disinfected; the bilge water shall be removed before the general disinfection of the ship.

Suspected ships shall be subjected to a simple medical visit, but the passengers' personal effects and those of the crew will have in every case to be disinfected.

Special measures will be taken by each Government for the ships conveying emigrants or found to be in bad hygienic condition.

Ships declining to undergo such measures will have to land their passengers and goods. The former as well as the latter will have to undergo the regulation measures, after which the ships may resume their voyage.

Such are the prescriptions for European arrivals. Those for extra-European arrivals have next to be enumerated. Meanwhile the importance of both groups of measures lies in this, that after their adoption the diplomatic section of the Conference will digest them in a species of international code which will without question be accepted by all the States represented at the Conference, including those—viz., Turkey, Great Britain, and Sweden and Norway—which hitherto have not adhered to the Paris Convention. These Powers, in fact, have, through their delegates, given official adhesion to the aforesaid Convention at the Conference now sitting.

The measures of non-European application for the prevention of the "pestis" are the following. At the ports of departure there will be made an obligatory hygienic visit to every individual at the moment of embarkation, followed by a rigorous compulsory disinfection of all articles, whether infected or suspected. No one betraying symptoms of the "pestis" will be allowed to embark, and as for pilgrims, they will have to show that they have the means necessary for the voyage to the holy places, for their sojourn thereat, and for their return therefrom.

For the passage of ships through the Suez Canal, those ships which are "recognised" shall have free and immediate passage from the port of departure, but will not be able to pass at Suez unless they have for ten days at least been *en route* from the last port considered to be infected.

Those non-recognised or suspected, if they are provided with a physician and disinfecting apparatus, will be able to pass the canal in quarantine; others not so provided will have to proceed to the Sources of Mosé for disinfection and for sanitary overhauling. This regulation holds, also, in the case of postal or passenger vessels which have made a voyage of at least fourteen days.

Those, on the other hand, the voyages of which have been of less duration and which have passengers direct for Egypt, will disembark the same at the Sources of Mosé. They will be isolated for twenty-four hours, their effects will be disinfected, and then they will have free course like the vessels themselves.

The infected vessels will be detained at the Sources of Mosé. Patients suffering from the "pestis" will be disembarked and isolated in hospital; the other passengers also disembarked and isolated under surveillance for a period not exceeding ten days; all effects, goods, and the ship itself shall be disinfected. Greater consideration will be shown to passengers on ships having on board a physician and disinfecting apparatus.

The Conference proceeded to regulate in every detail the surveillance and disinfecting service at Suez and the Sources of Mosé. The visit will be by day. The medical service is entrusted to seven duly qualified officers—to wit, a physician-in-chief, with a salary of from 12,000 to 15,000 fr.; four subordinates, with salaries from 8000 to 12 000 fr.; and two auxiliaries, with a minimum salary of 6000 fr.

Similarly regulated was the passage of the Suez Canal in quarantine. When such passage is admitted notice thereof is telegraphed to the country interested, warning being given, under penalties, to those vessels which did not go to the port indicated by the port commandant, except in cases of *force majeure*.

Specially stringent measures are applied to pilgrim vessels so as to ensure their being in the best sanitary condition possible and to obviate in every way the risk of their diffusing the "pestis." The regulations are directed to the stage before departure and to that during the voyage in case of illness or death among the pilgrims, severe fines being imposed on the captains failing scrupulously to observe the regulations in question.

Regulations are also laid down for the hygienic surveillance applicable to pilgrim vessels in the sanitary station

Hosted by Google

of Caraman, the improvements to be introduced into it, and those to be inaugurated at other Red Sea stations.

As well for European as for non-European arrivals the trade in personal effects, carpets, rags, skins, and such goods as may easily convey the "pestis" is strictly forbidden.

By such legislation as the above loyally enforced the Conference expresses the hope that all risk of invasion from the "pestis," or the diffusion of the same in non-infected countries, will be obviated.

BUBONIC PLAGUE IN INDIA.

WHILE the progress of the plague shows signs of abatement in Bombay city, it cannot be said that it has undergone much change for the better in some other places. Still, it is confidently believed that the disease is beginning to die out; it spreads very slowly and remains localised in the Bombay Presidency and Lower Sind, and shows no sign of extending as an epidemic over India generally. It seems to us that there is a good deal of point and pertinence in the remarks of the *Saturday Review* of the 6th inst. in regard to the anxiety that is being shown on the continent of Europe to keep out plague by quarantining ships, disinfecting baggage, and fumigating cargo that comes from the East. Hong-Kong may, says our contemporary, be taken, for purposes of illustration, as a centre of infection in 1894. It is in communication by steam and otherwise with a large number of other ports on the east coast of China and with Formosa and Japan, with the Philippines, Borneo, Java, Saigon and the Straits, as well as with India and Ceylon. The disease already existed at Canton, whence it probably came to Hong-Kong. Two years later it broke out suddenly at Bombay, although there is very little merchandise made or prepared for shipment in Hong-Kong that would be likely to go to Bombay. Is not the disease, asks the *Saturday Review*, more probably carried on the persons of those infected than on merchandise as a vehicle, and then when such infected persons reach a place reeking with filth it finds a suitable habitat and flourishes vigorously? Be this as it may, there is no doubt in our minds that local conditions are a most important factor, that filth is the great fertiliser and the ground the vitaliser of the plague bacillus. Calcutta, we are glad to say, remains absolutely free from the disease. Very elaborate and stringent arrangements have been made all over India under the Epidemic Diseases Act to prevent the malady from spreading.

Lord Sandhurst (the Governor) has issued a notification appointing a special committee of four members—General Gatacre, Mr. Snow (commissioner), Surgeon-Major Dimmock, and Mr. James (municipal engineer)—to carry out, under the orders of the Government, stringent measures to suppress and prevent the spread of the plague in Bombay. These measures, the Governor states, should comprise organisation—first, for the discovery of all cases; secondly, for the treatment of all cases in the hospitals; and thirdly, for the gradual segregation, so far as possible, of those persons who have been living in the same room with the plague-stricken or have been in close attendance upon them. The committee are given the fullest powers to enforce the measures.

Dr. Yersin has arrived in Bombay from Saigon bringing a quantity of anti-plague serum with him. Professor Koch is expected to proceed to India as soon as he has completed his work at the Cape in regard to the rinderpest; and in the meantime M. Haffkine and Professor Hankin are actively prosecuting their researches, the former in the experimental preparation and application of a prophylactic antitoxin serum.

The Secretary of State for India has received an official telegram from the Governor of Bombay in continuation of the previous telegram of March 1st. "For the week ending March 5th the deaths from all causes in Bombay city were 1870, reported plague deaths, 635. For the week ended March 4th: 397 dwellings condemned, 115 recommended for alterations, tiles removed from 931, floors dug up in 560, and 1727 limewashed, 210 vacated, and 46 have been destroyed by fire. Notification issued under Epidemic Diseases Act places carrying out of measures to suppress and prevent spread of plague in Bombay city in the hands of executive committee of four, who are rapidly organising improved and extended staff for house-to-house visitation and general health department; also organising large extension of hospitals with segregation camps attached for occupants of infected rooms and houses, and measures for removal thereto of sick and probably infected.

"In Poona plague still very prevalent, and no sign of diminution. For Poona municipal and cantonment areas executive committee arranged, who are organising complete scheme for house-to-house visitation, hospital, and segregation camps, and removal thereto of sick and probably infected.

"In worst affected places in Thana district—namely, Bandra, Coorla, and Bhiwandi—active measures under European supervision have been in force for more than a week. In Bandra the number of cases has decreased; in Coorla and Bhiwandi increased. Plague has newly appeared in five more villages in Thana district, but total number of reported cases in the district very slightly exceeds those of previous weeks.

"In Surat district the number of cases and of places affected both increased; elsewhere in the Presidency proper the only local cases for week ended March 5th were: In Satara district, 13 cases, 11 deaths; in Ratnagiri district, 3 cases, 2 deaths; in Kolaba district, 25 cases, 20 deaths; in Kathiawar district, 2 cases, 1 death; in Baroda district, 16 cases, 13 deaths. Railway inspection in force at Ahmedabad, Bhusawal, Dhond, Hotji, Londa, as well as Kalyan and Palghar.

"Karachi plague deaths for week, 200. Local cases have occurred at Sukkur; elsewhere in Sind no further indications of spread. In Karachi more patients are being taken to hospitals."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6412 births and 3822 deaths were registered during the week ending March 6th. The annual rate of mortality in these towns, which had been 18·8 and 19·4 per 1000 in the two preceding weeks, declined again last week to 18·1. In London the rate was 17·4 per 1000, while it averaged 18·6 in the thirty-two provincial towns. The lowest rates in these towns were 12·6 in Derby, 12·9 in Croydon, 13·6 in Birkenhead, and 13·9 in Huddersfield; the highest rates were 20·1 in Birmingham, 21·4 in Plymouth, 22·7 in Salford, and 23·0 in Manchester. The 3822 deaths included 331 which were referred to the principal zymotic diseases, against 316 and 379 in the two preceding weeks; of these, 103 resulted from whooping-cough, 67 from diphtheria, 59 from measles, 45 from diarrhœa, 26 from "fever" (principally enteric), 20 from scarlet fever, and 6 from small-pox. The lowest death-rates from these diseases were recorded in Croydon, Sunderland, Norwich, and Newcastle-upon-Tyne; while they caused the highest rates in Blackburn, Bolton, Salford, and Plymouth. The greatest mortality from measles occurred in Salford, Bolton, and Plymouth; and from whooping-cough in Birmingham, Bristol, Plymouth, Swansea, Blackburn, and Burnley. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 67 deaths from diphtheria included 43 in London, 4 in West Ham, and 3 in Birmingham. Six fatal cases of small-pox were registered in London, but not one in any other of the thirty-three large towns. There were 43 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 6th inst., against 38, 34, and 43 at the end of the three preceding weeks; 6 new cases were admitted during the week, against 20, 3, and 18 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2746, against 3050, 2901, and 2817 on the three preceding Saturdays; 211 new cases were admitted during the week, against 226, 227, and 237 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 335 and 368 in the two preceding weeks, declined again to 307 last week, and were 273 below the corrected average. The causes of 57, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were

Hosted by Google

duly certified in West Ham, Portsmouth, Bristol, Manchester, Salford, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Halifax, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 28·8 to 25·3 per 1000, further fell to 24·9 during the week ending March 6th, but exceeded by 6·8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18·0 in Leith and 18·8 in Aberdeen, to 27·2 in Glasgow and 32·4 in Perth. The 743 deaths in these towns included 36 which were referred to whooping-cough, 30 to measles, 16 to diarrhœa, 5 to "fever," 5 to scarlet fever, and 4 to diphtheria. In all, 96 deaths resulted from these principal zymotic diseases, against 119 and 86 in the two preceding weeks. These 96 deaths were equal to an annual rate of 3·2 per 1000, which was 1·6 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 45 and 32 in the two preceding weeks, rose again to 36 last week, and included 24 in Glasgow and 7 in Edinburgh. The deaths referred to measles, which had been 42 and 30 in the two preceding weeks, were again 30 last week, of which 18 occurred in Glasgow, and 10 in Edinburgh. The 5 fatal cases of scarlet fever corresponded with the number recorded in the preceding week, and included 2 in Glasgow. The 5 deaths referred to different forms of "fever" exceeded the number in any recent week, and included 3 in Glasgow, where 3 of the 4 fatal cases of diphtheria were also recorded. The deaths from diseases of the respiratory organs in these towns, which had been 218 and 231 in the two preceding weeks, declined again last week to 203, but exceeded by 92 the number in the corresponding period of last year. The causes of 47, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 43·4 and 37·6 per 1000 in the two preceding weeks, rose again to 45·2 during the week ending March 6th. During the past nine weeks of the current quarter the death-rate in the city has averaged 40·9 per 1000, the rate during the same period being 18·7 in London and 22·7 in Edinburgh. The 303 deaths registered in Dublin during the week under notice showed an increase of 51 upon the number in the preceding week, and included 79 which were referred to the principal zymotic diseases, against 72 and 55 in the two preceding weeks; of these, 44 resulted from measles, 21 from whooping-cough, 7 from "fever," 4 from scarlet fever, and 3 from diarrhœa. These 79 deaths were equal to an annual rate of 11·8 per 1000, the zymotic death-rate during the same period being 1·6 in London and 3·6 in Edinburgh. The fatal cases of measles, which had been 43 and 34 in the two preceding weeks, rose again to 44 last week. The deaths from whooping-cough, which had declined in the three preceding weeks from 25 to 12, rose again to 21 last week. The 7 deaths referred to different forms of "fever" exceeded the number in any week during the current year; and the mortality from scarlet fever also exceeded that recorded in the preceding week. The 303 deaths in Dublin last week included 50 of infants under one year of age, and 49 of persons aged upwards of sixty years; the deaths of infants showed a slight increase, while those of elderly persons were slightly below those recorded in the preceding week. Fourteen inquest cases and 5 deaths from violence were registered; and 70, or nearly a fourth, of the deaths occurred in public institutions. The causes of 22, or more than 7 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during February in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·7 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 12·6, 10·7, and 9·0 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Kensington, St. George Hanover-square, St. James Westminster, Marylebone, Hampstead, St. Martin-in-the-Fields, and City of London; while they showed the largest excess in St. Giles, Bethnal Green, Poplar, Battersea, Camberwell, Greenwich, and Lee. Forty-eight cases of small-pox were notified in London during February, against 3 and 8 in the two preceding months; of these, 29 belonged to Camberwell, 6 to Strand, 5 to the Port of London, 2 to Stoke Newington, and 2 to Lambeth sanitary areas. There were 43 cases of small-pox under treatment in the Metropolitan Asylum Hospitals at the end of February, against 1, 3, and 8 at the end of the three preceding months; 53 new cases were admitted during the month, against 7 in January. The prevalence of scarlet fever showed a further decline from that recorded in recent months; this disease was proportionally most prevalent in Hackney, St. Giles, St. Olave Southwark, Battersea, Wandsworth, Greenwich, and Lee sanitary areas. The Metropolitan Asylum Hospitals contained 2775 scarlet fever patients at the end of February, against 3932, 3601, and 3246 at the end of the three preceding months; the weekly admissions averaged 228, against 356, 355, and 245 in the three preceding months. The prevalence of diphtheria in London differed but slightly from that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in St. George-in-the-East, Mile End Old Town, Poplar, Camberwell, Greenwich, Lewisham, and Woolwich. There were 855 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of February, against 777, 829, and 897 at the end of the three preceding months; the weekly admissions averaged 101, against 110, 119, and 105 in the three preceding months. The prevalence of enteric fever in London showed a slight further decline from that recorded in recent months; this disease was proportionally most prevalent in Chelsea, Stoke Newington, St. Luke, and Bermondsey sanitary areas. Erysipelas showed the highest proportional prevalence in St. Pancras, St. Luke, Shoreditch, Bethnal Green, Poplar, and Lee sanitary areas. The twenty-six cases of puerperal fever notified during February included 7 in Lambeth and 5 in Islington sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, Feb. 27th, the deaths of 6344 persons belonging to London were registered, equal to an annual rate of 18·5 per 1000, against 19·2, 17·6, and 18·2 in the three preceding months. The lowest death-rates during February in the various sanitary areas were 12·8 in Hampstead, 13·4 in Stoke Newington, 14·1 in Plumstead, 14·4 in Paddington, 15·1 in Lewisham, 15·2 in Chelsea, and 15·3 in St. George Hanover-square; the highest rates were 24·2 in Clerkenwell, 24·3 in Limehouse, 24·6 in City of London, 24·8 in St. George Southwark, 25·0 in St. Olave Southwark, 26·2 in St. Saviour Southwark, and 27·2 in St. George-in-the-East. During the four weeks of February 556 deaths were referred to the principal zymotic diseases in London; of these, 181 resulted from diphtheria, 175 from whooping-cough, 58 from diarrhœa, 52 from scarlet fever, 44 from measles, 40 from enteric fever, 4 from small-pox, and 2 from ill-defined forms of continued fever. These 556 deaths were equal to an annual rate of 1·6 per 1000; no death from any of these diseases was recorded during the month under notice in St. Martin-in-the-Fields; among the other sanitary areas they caused the lowest death-rates in St. George Hanover-square, Westminster, Hampstead, St. Saviour Southwark, and St. George Southwark; and the highest rates in St. George-in-the-East, Limehouse, Camberwell, Greenwich, and Woolwich. Four fatal cases of small-pox were registered in London during February, of which 2 belonged to Camberwell, 1 to Greenwich, and 1 to St. Pancras sanitary areas. The 44 deaths referred to measles were less than a third of the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Clerkenwell, Bethnal Green, Limehouse, and

* Including 51 cases of membranous croup.

† Including deaths from membranous croup.

Hosted by Google

Poplar sanitary areas. The 52 fatal cases of scarlet fever were 24 below the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 181 deaths from diphtheria were 36 above the corrected average number; this disease was proportionally most fatal in Shoreditch, Bethnal Green, Mile End Old Town, Rotherhithe, Camberwell, Lewisham, Woolwich, and Lee sanitary areas. The 175 fatal cases of whooping-cough were 102 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. James Westminster, Newington, Camberwell, Greenwich, and Plumstead. The 40 deaths referred to enteric fever slightly exceeded the corrected average number; this disease was proportionally most fatal in Clerkenwell and City of London sanitary areas. The 58 fatal cases of diarrhœa almost corresponded with the corrected average number. In conclusion, it may be stated that the mortality in London during February from these principal zymotic diseases was more than 26 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to births registered, was equal to 126 per 1000 during February, and was below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Hampstead, St. Pancras, Stoke Newington, St. Martin-in-the-Fields, Strand, Mile End Old Town, and Woolwich; and the highest rates in St. James Westminster, St. Giles, Clerkenwell, Limehouse, St. George Southwark, St. Olave Southwark, Rotherhithe, and Lee.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN A. W. BEWLEY and Surgeon-Major S. Westcott have arrived in Dublin for duty.

Surgeon-Lieutenant-Colonel J. Ring to be Brigade-Surgeon-Lieutenant-Colonel, vice E. Townsend, promoted. Surgeon-Captain James W. Jennings is seconded for service with the Egyptian Army.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Colonel W. P. Warburton, Inspector-General of Civil Hospitals, North-Western Provinces and Oudh, is appointed to officiate as Director-General, Indian Medical Service, and Sanitary Commissioner with the Government of India, during the absence on deputation of Surgeon-Major-General J. Cleghorn, or until further orders. Brigade-Surgeon-Lieutenant-Colonel T. H. Hendley, C.I.E., Residency Surgeon, Jeypore, and Administrative Medical Officer, Rajputana, is appointed to officiate as Inspector-General of Civil Hospitals, North-Western Provinces and Oudh, during the absence on deputation of Surgeon-Colonel W. P. Warburton, or until further orders. Surgeon-Captain W. H. Ogilvie, Bengal Establishment, whose services have been temporarily placed at the disposal of the Chief Commissioner of the Central Provinces, is posted to the Jubbulpore District, on special famine duty. Surgeon-Lieutenant R. F. Standage is appointed to be District Medical Officer, Sholapore. Surgeon-Lieutenant-Colonel J. McCloghry to be Civil Surgeon, Kurrachee. Surgeon-Major W. H. Burke to be Medical Officer to the Kathiawar Political Agency and in charge of the West Hospital, Rajkote. Surgeon-Captain J. B. Smith and Brigade-Surgeon-Lieutenant-Colonel C. T. Peters have respectively delivered over and received charge of the Bijapore Prison. Brigade-Surgeon-Lieutenant-Colonel C. T. Peters and Surgeon-Lieutenant-Colonel H. McCalman have respectively delivered over and received charge of the Dharwar Prison.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Staff Surgeon M. J. McCarthy, M.D., to the *Wildfire*, for Yarmouth Hospital. Surgeons: J. W. W. Stanton to the *Plassy*; R. S. Bernard to the *Pigeon*; H. A. Julius to the *Magdala*, additional for disposal; W. R. Center to the *Cambridge*; W. S. H. Sequeira to the *Seaflower*; J. C. G. Reed to the *Martin*; W. M. Keith to the *Nautilus*; W. E. Mathew to the *Pilot*; W. H. Thomson to the *Lion*; W. D. Adams to the *Sealark*; A. T. Wyzard to the *Wanderer*; and Cornelius Bradley to the *Melampus*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant F. J. L. Warwick to be Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 4th Lancashire: Surgeon-Captain T. B. Grimsdale, M.B., resigns his commission. *Rifle:* 2nd Volunteer Battalion the Royal Scots Fusiliers: Surgeon-Lieutenant J. Highet, M.D., resigns his commission. 1st Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant E. R. W. Spratly resigns his commission.

THE WRECK OF THE "WARREN HASTINGS."

The public generally, as well as the army particularly, will feel grateful to the Queen for the telegram expressive of Her Majesty's appreciative recognition of the admirable discipline and conduct of the troops belonging to the King's Royal Rifles and the York and Lancaster Regiment on the occasion of the wreck of the *Warren Hastings*. There is no need to enter into the details of the occurrence, for they are probably fresh in the recollection of most of us. It may suffice to say that nothing was wanting to make up a situation that would try the nerves of the strongest, and that any want of discipline would most probably have been attended with terrible results. There was a strong squall blowing with heavy rain when the ship struck. The soldiers in obedience to orders fell in on the main and troop decks, so as to leave the upper deck free and allow of preparations being made for disembarking; meanwhile, darkness came on and about a thousand men formed a gangway and passed the women and children along, and they were all safely landed on the rocks. The ship was at an angle of about 50°, and had there been any pushing or struggling a number of lives must inevitably have been lost, but there was none; the most perfect discipline was maintained. The position of the engineers in charge of the ship's engines on such occasions as these, or on board one of Her Majesty's ships during a naval action, is one of the most trying that can be conceived, and the "greasers," as such men are often chaffingly nicknamed, who do their duty in times of the gravest danger are among the grandest fellows in existence; they nobly stuck to their work on this occasion, and the coolness and conduct of all, especially of the captain of the ship, seem to have been admirable. On reading a description of an occurrence of this kind the destruction of the *Birkenhead* is called to mind. If we remember aright, the account of that disaster and of the bravery and grand discipline displayed by our troops on that occasion was, by order of the King of Prussia, read out to his troops on parade.

A NEW HOSPITAL FOR WOMEN AT ALDERSHOT.

The wooden hospital which for years has done duty at Aldershot camp for the benefit of the soldiers' wives and families is to be superseded by a new extension of the Cambridge Hospital. Her Royal Highness the Duchess of Connaught laid the foundation-stone of the new wing on March 1st, and when finished the new buildings will consist of two wings, or eleven wards, with a total accommodation of fifty-four beds, in addition to the quarters for nurses and staff. An advantage of the new arrangement is that the staff of the whole hospital will be consolidated and will work in touch with each other.

DEATHS IN THE SERVICES.

Surgeon Richard Henry Way, R.N., at Warrigi, on service with the Benin Expedition, on the 21st ult., aged twenty-nine years. He was appointed Surgeon in 1894.

Brigade-Surgeon-Lieutenant-Colonel D. A. Leslie, A.M.S., medical officer in charge of troops, Perth, on Friday morning, March 5th. He served in the Bhootan Expedition in 1865, including the re-capture of Dewangiri, and was awarded a medal, with clasp.

THE OPERATIONS IN MATABELELAND AND MASHONALAND.

The following members of the medical profession have been mentioned in despatches:—Surgeon-Lieutenant-Colonel J. A. Gormley, A.M.S., Surgeon-Captain Hale, A.M.S., Mr. Strong, Mr. Sutcliffe, and Mr. Redpath.

The *Bombay Gazette* says:—"Surgeon-Major Hatch, Principal of the Grant Medical College, with two of his servants, Surgeon-Captain Childe, Professor of Pathology in the same college, a Parsee medical man, a Parsee member of the corporation, a Mohammedan veterinary inspector in charge of the Lazaretto at Sewri, and a Maratha Hindu in municipal employ have been inoculated against the plague at the Petit Laboratory, Grant Medical College, Byculla, by

Hosted by Google

Professor Haffkine. The learned professor, who has prepared the prophylactic lymph, was the first to set the example of making the experiment on the human subject by inoculating himself. It is satisfactory to know that representatives of the various races and creeds in Bombay have not hesitated to follow their example."

The Hants Company Militia Medical Staff Corps will assemble at Netley on May 1st for sixty-three days' preliminary drill, recruits' musketry to take place at Browndown Fort, Gomer. The annual training of twenty-seven days will be as follows: Assembly July 3rd, 1897; dismissal, July 29th, 1897; place of assembly and training Netley.

An obstinate outbreak of measles has taken place on the *Impregnable* training ship at Devonport. There were seven cases removed to hospital on one day last week, and there have been several cases since.

The s.s. *Britannia* has brought home 296 patients for the Royal Victoria Hospital.

Correspondence.

"Audi alteram partem."

"A QUESTION FOR ANÆSTHETISTS."

To the Editors of THE LANCET.

SIRS,—In my short article published in THE LANCET of Feb. 20th under the above heading I drew attention to the fact that the apparatuses used by anæsthetists were in hospital practice passed from patient to patient without being subjected to sterilisation, and that I believed the lung affections commonly attributed to the anæsthetic might very possibly be due in part to infected apparatus. I stated that, whereas in almost every other department rapid progress had been made of late in rendering the patient safer by thorough disinfection of his environment, the danger to the patient of directly applying over his nose and mouth an inhaler that had been used by others had not yet presented itself apparently to the workers in the special field of anæsthetics. To many with whom I have spoken my suggestion has presented itself with such force that they have expressed astonishment that the possibility of danger from this source had occurred to no one before. True, some of your correspondents may have adopted ordinary everyday sort of cleanliness, but sterilisation of apparatus seems never to have occurred to anyone. Now, as all sepsis treated by physicians (I use the term to include all bacterial infection—typhoid, tubercle, &c.) must enter by the respiratory or alimentary tract, the danger of half-stifling a person with an apparatus impregnated by some other person's excreta (breath, sputum, or vomit) should, one would hope, appeal to something more than the imagination of an individual. Take, for instance, the case I had on the operating table a few days ago—a man I have been protecting from tubercle for more than eight years. He came first with tuberculous disease of the tarsus, which, under rest and mercury, subsided, and he was well for two years. He got a situation, the disease returned, went on to suppuration, and involved his ankle. He now had distinct signs of phthisis, blood-spitting, and consolidation of one lung apex. I amputated the foot and the phthisis remained quiescent for four years, though he continued to cough and physical signs were distinctly evident, yet he made rather than lost flesh. A few months ago he accidentally hit the knuckle of his left forefinger with a mallet. An indolent pulpy swelling formed, tuberculous teno-synovitis around the extensor tendon ensued, and I advised the pulpy mass to be all dissected away. Chloroform was given to avoid irritating his tuberculous lungs. Junker's apparatus was used, consisting of a mask, with a somewhat complex top through which the vapour was forced, and whilst he was being put under the patient continually coughed, and on one occasion spat into the apparatus. Think of the next patient for whom this apparatus is used! Why, it is Villemin's original experiment over again without the record of the result, for this distinguished Frenchman first clearly showed the infectiveness of tubercle by tying masks infected with tuberculous sputum over dogs' noses. At the present time no one keeps the after-records of the innumerable experiments thus being daily made, and tubercle is too slow in its development to attract attention by immediate results.

The object of my article was not to impute blame, but to stimulate invention and to insist on greater cleanliness in the use of anæsthetic apparatus. I readily testify to the immense advance made in the more careful administration of anæsthetics during the last ten or fifteen years owing to the employment of gentlemen as special administrators and teachers in this branch. Many of these I count as personal friends, but I doubt if special anæsthetists have much opportunity of studying the after-results of their administrations or of distinguishing between the results of the operation and those of the anæsthetic. It is satisfactory to learn from your correspondence of last week that at one hospital the face-pieces and inhalers are cleansed every day after use, so that the first patient in the morning is lucky enough to have a clean apparatus. This is more than happens at many places, and in large hospitals, where there are often half a dozen operations going on at the same time, and each surgeon has two, three, or four cases in succession, the inhalers go from patient to patient without any attempt at sterilisation. It is agreeable also to note that a gentleman who scouts my suggestion of infection by inhaler as "not even a scientific possibility" goes on to say that "every inhaling bag, mask, and face-piece should be thoroughly washed, or scalded out if possible, between each case." A little more than this is just what I am contending for. I hold that every inhaler should be of such construction as to allow of complete sterilisation, and that this process should always be carried out before it is employed a second time.

It has been suggested to me that I ought not to criticise without being prepared with an alternative contrivance. My idea is that all masks should be made of toughened glass capable of being boiled, and that where a sponge or flannel receiver is employed an asbestos web which may be raised to white heat without injury should be substituted. Where respiratory bags are employed they should be made of red rubber or other material capable of being turned inside out and of resisting injury by boiling.

I am, Sirs, yours faithfully,

R. CLEMENT LUCAS, B.S. Lond., F.R.C.S. Eng.,
Surgeon to Guy's Hospital.

Wimpole-street, W., March 5th, 1897.

WATER-SUPPLIES AND MORTALITY FROM FEVER.

To the Editors of THE LANCET.

SIRS,—During the last two years it has been part of my official duty to investigate the variation and increase throughout Europe for the past half-century at certain periods of life of the rate of mortality among adult males. Incidentally I was led to examine into the relation between water-supplies and enteric fever. As Parliament will have in the coming session many projects for water-supply to large communities before them, I venture to ask that you will grant me a short space in your columns so that I may briefly place before your readers the rate of mortality in 1896 from fever obtained from various official Government statistics. For comparison and to avoid decimals I have computed the mortality from fever per 1,000,000 living from a few typical towns the water-supplies of which are drawn from widely different sources.

		Dorking (greensand; mean of last ten yea s)	70

Unfortunately I have been limited in my selection of English towns, as accurate information is at present unattainable owing to the fact that the Registrar-General's mortality returns for the whole of England and Wales for 1896 will not be published until 1898. It will be observed that towns drawing their water-supply from sands, melted snow, and rivers have a lower rate of mortality from fever than those drawing their supply from either chalk, peat, or moorland gathering ground.

Dr. Seaton, the county medical officer for Surrey, has shown in his report on water-supplies that the mean death-rate from enteric fever for the last decade for Epsom and Sutton, which obtain their water-supply exclusively from the chalk, was at the rate of 190 per 1,000,000 living, and that this rate was an increase over the mean death-rate of the previous decade. The mortality from fever at Reigate, another chalk supply, was 160. On the other hand, Dorking, which formerly derived its water from the chalk, but now obtains its water from greensand, had a mean death-rate of 70 per 1,000,000, and shows a material diminution in the death-rate from this cause. In Chertsey, which derives its supply principally from the Thames, the mean death-rate from typhoid fever was 90 per 1,000,000 during the same period. The chalk in the neighbourhood of our large towns is being progressively contaminated by the establishment on its surface of sewage farms, cemeteries, and even by the drainage from isolation hospitals. The rainfall percolating through a soil thus polluted must pass in a contaminated condition through the joint planes and fissures down to the subterranean streams, the reservoirs of this water-bearing stratum. Surely the time has arrived for legislation for the protection against further injury to this important source of supply. A glance at the foregoing table suggests the probable existence of a law which further investigation will either confirm or refute.

In conclusion, I trust that I have made out a *primâ-facie* case for an exhaustive Government inquiry as to the cause of the susceptibility to and immunity from fever amongst populations deriving their water-supply from various sources. Moreover, it is at least open to discussion whether municipal bodies, who are empowered to levy rates for sanitary administration, are suitable authorities to act as amateur managers of trading monopolies.

I am, Sirs, yours faithfully,

A. H. SMEE, M.R.C.S. Eng., F.S.S.,
Deputy Chairman and Chief Medical Advisor, Gresham Life Office, St. Mildred's House, Poultry, E.C.

DR. CULLINGWORTH AND PUERPERAL FEVER: A REFUTATION.

To the Editors of THE LANCET.

SIRS,—Attention has been called to remarks made by Dr. Cullingworth published in your issue of March 6th. As these are so unjust and so calculated to reflect discredit upon practitioners in private practice, I challenge their accuracy.

Dr. Cullingworth states: "Although puerperal fever has practically become a thing of the past in our lying-in hospitals ..... it is impossible to ignore the fact that there has not been a corresponding diminution of mortality from puerperal fever *in ordinary private practice*.' He does not produce any statistics to prove his assertion. His address will have attained the expected results if it is circulated among ladies connected with lying-in hospitals and midwives and so used to blast the good name of practitioners in "ordinary private practice." If the order has gone forth that no such a thing as puerperal fever *must* be officially recognised *in lying-in hospitals*, then I can understand the statement that puerperal fever is "practically a thing of the past." If the diagnosis of puerperal fever is left chiefly to midwives in hospitals, will it be recognised? It is not. Medical Officers of Health have complained of the ignorance shown by medical practitioners diagnosing cases of infectious fevers. It follows if practitioners are so badly educated that they can not *diagnose* puerperal and other fevers, the midwife will be more ignorant. Dr. Cullingworth has failed to tell us how many women *suffered from* puerperal fever, reference being made only to the number who *died*. Let us have a little light upon the number *attacked* in hospital.

The statistics relating to lying-in hospitals are misleading. Unfortunately, I had, when giving evidence before the Select Committee of the House of Commons, to show how sadly unreliable and wide of the truth these hospital statistics are. I pointed out that in most lying-in hospitals (*a*) all unmarried women are rigidly excluded, thus keeping out the illegitimate class, who have an exceptionally high death-rate; (*b*) that in others, those women pregnant for the first time are excluded, thus shutting out those who give the highest death-rate of all—1 in 15; (*c*) that women who had no child living were refused help, thus excluding those malformed or who had some maternal disease which had caused the infant's death; (*d*) that a large number of women leave the lying-in hospital within from seven to ten days after confinement, and are afterwards lost reckoning of; (*e*) that confined women attacked with fever, &c., are removed from the lying-in to a medical or surgical ward or to a fever hospital and are thus lost sight of; (*f*) that the rule of the Registrar-General is frequently ignored which requires that when a woman dies within thirty days after her confinement this fact should be stated in the certificate of the cause of death: and (*g*) that when lying-in hospitals have a low death-rate this is due altogether to the fact that medical practitioners are called in to assist by operation, &c.

The Rule of the Registrar-General of Deaths is:—"Whenever childbirth has occurred within one month before death, the fact should *invariably* be certified, *even though* it may appear that the childbirth has no connexion with the cause of death." How can lying-in hospital statistics include all, up to one month, when many of the women leave within seven to fourteen days after childbirth? Practically all who have left, and who die within seven or fourteen days are omitted. Mr. E. Hart, in his book "Compulsory Notification in England and Wales," p. 45, states that puerperal fever is not even notified, and in this he is backed up by the opinion of health officers. Neither are the deaths from puerperal fever notified to the Registrar. Of what use therefore are such statistics of puerperal fever? None whatever, except to make our profession a laughing stock. Even Dr. Cullingworth does not understand these statistics, as he says: "Deaths occurring in childbed from pre-existing disease, or from causes not directly connected with childbirth, though taking place during labour, or during the lying-in period, are left out of account." The very opposite is the case, as will be seen from the above quoted Rule. If his lapse is used in connexion with lying-in hospital statistics it furnishes another instance of the unreliability of hospital statistics. With such a proviso all deaths could be evaded.

Dr. Cullingworth, although he speaks of "Puerperal fever," fails to tell us what is "puerperal fever"? I have asked for a definition, but the "learned body" of persons connected with the Obstetrical Society seem to be as shy of defining it, as they do of the term "natural labour"! Puerperal fever means—fever in a puerpera. In the 2nd Edition of "The Nomenclature of Disease" page 9 it is stated "the term puerperal fever should no longer be used." Yet we have Dr. Cullingworth using it, and using it so as to reflect discredit upon practitioners. In the 1893 Report of the Registrar General we have the statement that 20,856 infants died from "convulsions," and 4,057 from "teething." These words—"convulsions" and "teething" no more give the true and accurate causes of death than do the words "puerperal fever." As regards the prevention of puerperal fever Dr. Cullingworth has the great supposed panacea of

Hosted by Google

the hour—antiseptics. Dr. Bantock has urged absolute cleanliness in our work. This is all that is required. However, as some clergy have entered in House of Lords floating in on "the odour of sanctity," and as some have become "Peers through Beer" so I suppose others hope to obtain popularity by wildly suggesting antiseptics for everything—lying-in cases included.

It is sad that Dr. Cullingworth's mind is so saturated with antiseptics. He says all the puerperal fever deaths are chiefly due to the want of antiseptics. I would, however, rather ask him and others to widen their range of observation and to consider whether the chief causes of puerperal fever and the deaths therefrom are not due to the lamentably poor training which Students now receive in Obstetrics. This is the pivot of the whole question. How many students ever see a case of puerperal fever? If Dr. Cullingworth's statement as to this fever being absolutely "unknown" in hospitals is accurate, it follows that it is an impossibility for them to see a single case! This, too, although from 1871 to 1893 no less than 48,375 mothers died from puerperal fever, and 50,211 from the accidents of childbed. Happy hospitals! When in 1889, I began to look into this sad question of puerperal mortality, I thought it better first to find out something as to how students were "educated"—if I may use that word. The following table shows how students were educated then:—

Name of Examining body.	Lectures in Midwifery, Diseases of Women and infants.	Clinical instruction at Maternity Hospital.	Number of confinements to be attended by each student.
Royal Colleges of Physicians and Surgeons, London	3 months and	3 months	and 20
Society of Apothecaries	" " "	" "	" "
University of London	1 course	—	20
University of Oxford	0	0	0
University of Cambridge	1 course	—	20
University of Durham	3 months and	3 months	and 20
Victoria University	6 " and	3 "	and 20

Royal University ...	6 " and	6 "	and 20
University of Dublin	6 " and	6 "	Not stated

In November, 1890, I memorialised the Medical Council upon the death-dealing state of affairs as shown by the above table. As nothing was done the subject came up again before the Medical Council; and again in 1895. The recommendation of the Council and the Examining Bodies, as agreed upon in 1888, was, that any student was to be admitted to the "final" who showed he had conducted three labours! Three labours! Is it any wonder that at least sixteen women each day die in England from what we dishonestly term "accidents of childbirth"? Would not a little "more light," instead of the antiseptic craze, lessen this terrible death-rate? Fancy the University of Oxford up until 1895 granting its degree to men who had not to present any certificate of theoretical or practical instruction in midwifery! Fancy the Scottish Universities demanding attendance upon 6 labours only! The wonder is that the maternal death-rate is not treble what it now is. Fortunately the Medical Council has withdrawn its death-dealing Resolution, and it now Recommends that the student must have been present at not less than 20 labours (instead of 12) and must have conducted throughout at least 5 labours (instead of 3). This is a magnificent piece of herculean work for the Medical Council, and we must, at present, be content, that it has shown that after five years' pushing it can move! Did the public know the real reason of its not having moved, I think it would be hissed out of existence. The next method by which Dr. Cullingworth can lessen the puerperal mortality would be by increasing the stringency of the medical examinations. If fewer men were "qualified to kill," and more "qualified to cure," the death rate and sick rate would diminish. But what can we expect when we are told by men that the adding of a teaspoonful of carbolic acid to a pint of water is to abolish puerperal fever? It sounds rather like Count Mattei's "green electricitus."

Dr. Cullingworth thinks the great cause of puerperal fever is untrained midwives, and that if they were only licensed, fever would diminish. That is, the mere placing of the "10,000 to 15,000" of the present untrained midwives,—whom he says are doing such harm,—would stop the trouble! This is simple! It is almost as ghastly as the Rules of the Obstetrical Society—which provide that any woman may enter for the Diploma in Midwifery of the Obstetrical Society who can show that she has examined and attended 20 labours, under the care of another midwife, or matron of a hospital. Such, according to the President of the Obstetrical Society is the way in which the puerperal mortality is to almost disappear. Dr. Cullingworth refers to himself as—"a responsible teacher of midwifery." Also he says, "the Obstetrical Society has always been foremost in the effort to reduce the present terrible mortality from childbirth." This seems strange in face of the above fact, that any woman who has attended 20 confinements with a midwife—not having attended one solitary lecture—is qualified to practise midwifery. However, here is the test of this "foremost" policy. Clause 3 of the present Midwives Bill proposes to punish any person who unlawfully uses the term "midwife" with a fine not exceeding £5. Clause 13 of the Plumbers Registration Bill proposes to fine any person using unlawfully the title of plumber a sum not exceeding £20. This is a fair sample—the difference between £5 and £20—of the "foremost" anxiety of the Obstetrical Society to "diminish child-birth mortality." He also quotes Dr. Williams as stating that midwives "often spread puerperal fever broadcast and are often not interfered with." If this be true I think the medical officer for Glamorgan is hardly doing his duty; because such midwives can be brought before the coroner or magistrate and suspended from acting. Again, reference is made to certain districts in Wales in which the people have not the means of employing a practitioner. Need I repeat that each Board of Guardians in Wales has now power to pay a fee of from 20*s.* to 40*s.* to any practitioner they appoint to act in all poor confinements. If the practitioners and people of Wales fail to do so, then let them take the consequences. I am, Sirs, yours truly,

Liverpool, March 10th, 1897. ROBERT R. RENTOUL.

THE INCIDENCE OF PUERPERAL FEVER.

To the Editors of THE LANCET.

SIRS,—In reading Dr. Cullingworth's article on Puerperal Fever and after studying the accompanying map of London it has struck me that the position of the hospitals may have some effect on the incidence of this disease. If anyone will mark in his copy of the map the great teaching hospitals he will see that, with the exception of St. Mary's Hospital and the Royal Free Hospital, they are all situated in the lightly shaded districts—i.e., in those freest from this complaint. Is it not probable that the freedom from puerperal fever is due to the fact that the poorest and dirtiest persons around the hospitals are attended by the students, whilst in the outlying districts this class of individual is at the mercy of the untrained midwife?

I am, Sirs, yours faithfully,

H. BEALE COLLINS,
Medical Officer of Health, Kingston-upon-Thames.

Kingston-hill, March 5th, 1897.

THE MEDICAL STAFFS OF HOSPITALS AND HOSPITAL ABUSE.

To the Editors of THE LANCET.

SIRS,—In the first leading article in THE LANCET of March 6th, in dealing with this important question you give special prominence to certain opinions which I am supposed to hold in regard to it, which, to be quite accurate, require elucidation. I hope, therefore, you may be willing to open your columns to a discussion on the points raised, and that you will permit me to set forth a few practical aspects of the problem which must be realised and understood if any attempt at reform is to be fruitful in results.

First of all, it is essential to recollect that at the present moment the metropolitan hospitals need, as Dr. Glover has often insisted, "less criticism and more cash." If the present efforts to place the metropolitan hospitals once and for all upon a sound financial basis are supported, as they ought to be supported, by every intelligent person who realises the necessity for the maintenance at their full capacity and high administrative excellence of our London hospitals to-day, then, but only then, will all the money that is required be forthcoming. Any person, therefore, who obtrusively endeavours to draw the herring of controversy across the path to assured financial safety for our hospitals must, to say the least, be suspect as to his motives, and cannot claim now, much less if and when the money is raised, that he is entitled to be heard as a critic who has the well-being of the hospitals really at heart. If once the financial security of our hospitals is assured, every needful alteration of system can rapidly be secured if the profession so wish.

What the friends, and also the critics of hospitals, can very usefully do at the moment is, whilst leaving the time between now and Accession Day free to those who are endeavouring to raise money for the hospitals, to occupy their energies in organising, as you suggest, a conference of the coolest heads of the profession for the purposes of discussion, so as to secure united action and agreement as to the best course to pursue in the interests of everybody. If this is done, the managers of the hospitals, as well as the managers of the various organisations which exist for raising money on behalf of hospitals, will be in a position to deal with any existing abuses that may call for reform. In such circumstances the whole of the questions raised could be treated on their merits, seeing that the attitude of the medical profession will then for the first time in the history of this question, be accurately ascertained and demonstrably provable.

The union of the profession on the subject, or at least the union of those members of the profession who hold office as honorary medical officers of the metropolitan hospitals, is the keystone of the arch of reform. The managers of hospitals, or the most capable and important of them, are as anxious as anyone to reduce the number of out-patients, but they feel that they are not in a position to do this because the means of reduction rests rather with the medical profession than with the lay managers of hospitals to which medical schools are attached. At the present time the medical profession render eleemosynary service to the hospitals, and the governing bodies feel that, so long as the medical profession attached to hospitals desire,—as the managers believe them to desire—to encourage an increase in the numbers of out-patients admitted he managers do not see how it is possible for them, in face of their honorary medical staff's attitude on the question, to reduce the number of out-patients. Experience seems to prove that the managers are justified in their view, for the report of the evidence given before the Lords' Committee on Metropolitan Hospitals, by those who were responsible for the medical teaching at the London hospitals, shows these witnesses to have expressed the opinion, that to reduce the number of the out-patients would be to curtail, not the abuses, but the use of the out-patient department for clinical purposes. This testimony is the more remarkable from the circumstance, that it is in distinct conflict with the findings of Sir William Fergusson's Commission on Out-patient Hospital Administration in the Metropolis in 1871. That Commission recommended, amongst other excellent things, the two following, the adoption of which, in my judgment and experience, are essential to the effectual removal of the abuses complained of:—

1. In order to improve the clinical teaching of the out-patient departments of the special and general hospitals, it is desirable to curtail the present unrestricted system of gratuitous relief, partly by the selection of cases possessing special clinical interest, and partly by the exclusion of those who, on social grounds, are not entitled to gratuitous medical advice. 2. The payment of the medical staff engaged in out-patient work.

It will be seen that the first of these recommendations, made in 1871 on the highest medical authority, embodies the opposite view to that held by several of those who were responsible for the medical teaching at the London hospitals twenty years later. The second recommendation is further wise, because it would afford an opportunity, to make the out-patient department available under proper regulations, not only for the training of students, but for the practical instruction of post-graduates, so that the general body of the profession might not only be helped directly by the facilities for instruction thus afforded to them, but indirectly by securing that none but suitable cases—that is, suitable from a medical and social aspect—were dealt with as out-patients. I do not think it is sufficiently recognised at present by the honorary medical staffs of the hospitals, that it is their duty to see that the mean of efficiency of the general medical service available for Londoners, in the poorer districts especially, shall attain a much higher standard than at present exists. None who have been attached to a large London hospital for a number of years can have failed to realise this fact, for they must have had many cases brought to their notice which were under treatment before coming to the hospitals, and the condition of which when they arrived at the hospital gates proved the soundness of the view so generally held by the poor, that if they have anything the matter with them the best thing they can do, if they want to get speedily well, is to go straight to the hospital. I have ventured to put this point forward because I occupy a somewhat neutral position in the matter, and it is essential that we should look facts in the face.

If we can once secure the union of the profession on the subject, or, as I have said, at least the union of those members of the profession who are attached to hospitals in London, the reduction of the number of out-patients and the removal of the real abuses of out-patient departments could then be enforced in a businesslike manner without difficulty or hardship. If the general body of medical practitioners whose practices have been injured by the present system of out-patient relief choose to coöperate together and to make adequate representations to the members of the honorary medical staff of each of the great hospitals, the attitude of members of those medical staffs which still hold to the opinion that a continuous increase of out-patients is essential for clinical purposes must alter. With such a change of opinion the managers would be able to secure that the out-patient departments should henceforth be conducted with some regard to the interests of the great body of the medical practitioners as well as of the public themselves. There are several out-patient departments where an attempt at a remedy has long been under trial, notably at St. Thomas's Hospital and elsewhere. A brief account of the system of out-patient relief at every London hospital to-day would prove valuable at the moment.

I am of opinion, as I have always been, that the kindest thing to the patients and the best thing for the hospitals and the profession would be to determine to close the whole of the London out-patient departments for six months, providing, but only providing, that each hospital made adequate arrangements by which they could guarantee that every urgent medical and accident case would be treated promptly throughout the period of experiment. I hold to this opinion because I find, from the visits I have paid to the out-patient departments during twenty years, (I am not speaking here of the casualty departments, which in certain parts of London are as essential to our social well-being as the very air we breathe, for reasons which I need not go into now), that a very large number of applicants who frequent them are not in urgent need of medical treatment. Hence, I believe, if we were to close the London out-patient departments, with the safeguards already referred to, and to watch the effect of this closure upon the people, we should find, that the majority of the patients would in a few weeks adapt themselves to the altered circumstances. They might even realise, as Sir William Gull once said, that there was a limit to the craze for physic, and that as far as physic was necessary it could be procured for a payment within their means without resorting to the hospitals at all.

I should like to formulate certain other proposals for with the out-patient question, but I have already occupied

Hosted by Google

too much of your space. I will only, then, venture to say, that the statement you quote as mine, to the effect that the Council of the Hospital Sunday Fund is only a collecting body, requires modification. I find from the shorthand writer's notes of the speech to which you apparently refer (July, 1896) that the words used were as follows: "I think that the solution of the difficulty cannot be looked for from the council (of the Sunday Fund), which, after all, is a collecting body more than a criticising body. The solution must come from the leaders of the medical profession themselves and from the body of general practitioners who suffer from the growth of the out-patient department. ..... It is the duty of the medical profession to look this matter in the face and to deal with it on some principle which will reduce the evil and secure the proper interests of the medical men and the public. Until this has been done I hope the Council of the Hospital Sunday Fund will be content to do its work of collecting money without indulging in criticisms which must necessarily be directed to points which it could not follow up by enforcing reforms of a sufficiently drastic nature ..... The managers of hospitals themselves cannot effectually interfere, until they have a request put forward in a practical form by their medical staffs, who have it in their power to remedy the existing difficulties." You will see that so far from "belittling the Council of the Hospital Sunday Fund or the religious bodies which so generously contribute to it," my speech really added to their importance by insisting that before any action was taken care should be exercised to secure that the Council possessed sufficient authority to ensure success. This policy, which Sir Sydney Waterlow, like myself has done his best to enforce for many years in regard to the Metropolitan Hospital Sunday Fund, has resulted in a number of improvements in the administration of the London hospitals, which have gradually attained so great an increase in efficiency that they may now be regarded, and with justice, as amongst the best administered institutions in the world.

I am, Sirs, your obedient servant,

HENRY C. BURDETT.

The Lodge, Porchester-square, W., March 6th, 1897.

THE PHYSIOLOGY OF THE VESICULÆ SEMINALES.

To the Editors of THE LANCET.

SIRS,—In his Hunterian Oration, as reported in THE LANCET of Feb. 20th, Mr. Christopher Heath quotes the following from John Hunter: "It is a discharge of mucus by the urethra which generally comes away with the last drops of urine, especially if the bladder is irritable, and still more at the time of being at stool, particularly if the patient be costive, for under such circumstances the straining or action of the muscles of these parts is more violent. It has generally been supposed that this discharge is semen, and the disease is called a seminal weakness; but it appears from many experiments that the discharge is undoubtedly not semen." Mr. Heath, so highly does he appreciate "the good common-sense teaching" of Hunter on this point, while according to his own showing he questions his authority or accuracy on many other points, affirms his acquiescence in Hunter's views as to the vesiculæ seminales. I have been in the habit for a long period of years of making microscopical and chemical examinations of the urine, and I have no hesitation in affirming as the result of that experience that both Hunter and Heath are in error. I believe that 50 per cent. of urethral discharges at stool under these circumstances contain spermatozoa in more or less abundance; but as to the pathological significance of their presence this is a totally different question. Unfortunately, on this and some allied sexual questions a silly professional *mauvaise honte* has consigned multitudes of young men to quacks, both within and without the profession, and left this subject as a fertile hunting-ground for the unscrupulous. For my own part, I do not think that the discharge of spermatozoa from the urethra at stool can be considered normal, and whether it absolutely has an influence on the sexual functions or not I am certain that many patients believe that it has. Certainly I have never witnessed any markedly serious consequences from the condition. I agree with Mr. Heath that the word "spermatorrhœa" should be eliminated from medical literature, and some years ago I suggested as a substitute the word "spermatorrhagia," which expresses a pathological condition of undoubted existence and no less undoubted gravity. There can be an excessive discharge of semen and a seminal incontinence prejudicial to health just as there can be an excessive drain of menstrual fluid and a too frequent occurrence of it noxious to health in the female. I do not think that there is a better established fact in physiology than that the vesiculæ seminales act as reservoirs for the seminal fluid. Their function is, in this case, absolutely parallel with that of the gall-bladder for the bile. They receive the seminal fluid from the testes and elaborate and perfect it as a secretion by the addition of a special secretion from their own walls. In the vesiculæ seminales the semen remains until it is expelled in sexual intercourse, or involuntarily discharged under the influence of a psychical erethism, especially during sleep, a condition which, within certain limits, is nothing more than absolutely normal in the continent after puberty. Like all the other organs in the body engaged in secretion and excretion, the vesiculæ seminales are excited to action by their special stimulus, and are therefore in connexion with corresponding centres in the cerebrum. During sleep the organic functions — those regulated by the sympathetic system — obtain an ascendency over those controlled by the cerebro-spinal system. While not absolute the distinction between the sympathetic and cerebro-spinal system is still convenient. Dreams are of two kinds: those induced by nerve stimulation and those arising from association of ideas. In this case a nerve impulse is conveyed to the brain from the engorged vesiculæ seminales. "A memory picture arises, a perception results" (Moll), and reflex action takes place through the spinal cord. The theory of the resorption of semen is entirely groundless, and consequently the outrageous treatment based upon it—viz., that of the late Brown-Séquard and his followers. Still, the semen becomes inspissated in the vesiculæ seminales according to the length of time that it remains there, and this is due to the resorption of its more watery portion just as a certain amount of resorption takes place in the larger bowel.

I am, Sirs, yours faithfully,

D. CAMPBELL BLACK, M.D. Glasg., F.R.S.Edin.,
Professor of Physiology in Anderson's College Medical School.
Glasgow, Feb. 20th, 1897.

P.S.—I should have noted that Hunter says that it is mucus which "generally" comes away from the urethra with the urine and at stool, and then he says the discharge is not "semen." If it is not "semen," and if it is not always "mucus," what is it?

LIGATURE OF THE SUPERFICIAL FEMORAL ARTERY FOR POPLITEAL ANEURYSM.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 27th Mr. Frederick Page records a case of Popliteal Aneurysm successfully treated by Ligature of the Superficial Femoral Artery in Scarpa's Triangle and states his own favourable experience of the results of the operation. Before deciding, as some surgeons have suggested, to abandon this simple operation for the far more difficult alternatives of ligature of the popliteal artery close above the aneurysm or complete excision of the aneurysmal sac, it must be shown that the ordinary method of treatment is not attended with the measure of success with which it is usually credited. Gangrene of the limb and recurrence of pulsation in the aneurysm are the two very opposite accidents which may follow the operation. Regarding gangrene, it may at once be said that it rarely follows the application of a ligature to the femoral artery for the cure of a popliteal aneurysm, and that on this ground alone no one will be disposed to condemn the operation. When, however, we come to consider the question of recurrent pulsation the position of the operation is not quite so sure. From the reports of St. Bartholomew's, St. Thomas's, and University College Hospitals published since 1886 I have collected thirty-one cases in which the femoral artery was tied at the apex of Scarpa's triangle for popliteal aneurysm. In twenty-three cases the aneurysm was cured without the occurrence of any complication. In two cases gangrene followed the operation and necessitated amputation through the lower part of the thigh, both patients recovering. In a third case amputation was performed a month after the operation for ulceration and anæsthesia

Hosted by Google

of the foot, probably caused largely by attempts to straighten the flexed knee. In the remaining five cases pulsation recurred in the aneurysm. In one of these the pulsation was slight, and was cured thirteen months after the operation by resting the limb in the flexed position for twenty-five days. In the second case the artery was tied without rupture of its coats; pulsation returned on the day after the operation and was successfully treated by exposing the artery, applying ligatures above and below the previous seat of ligation, and excising the intervening portion of the vessel. In the third case the recurrent pulsation was arrested by ligature of the popliteal artery above the sac, and in the fourth and fifth cases by excision of the aneurysm. We may, I think, fairly exclude the first two of these five cases, because in one so long an interval elapsed before pulsation returned, and in the other there is good reason for thinking that the lumen of the artery was only incompletely closed by the first ligature. This gives 3 cases of recurrent pulsation in a total series of 29 operations, or adding these cases to the twelve given by Mr. Page, 3 recurrences among 41 operations. Unless, therefore, the results in these two series of cases have been unusually satisfactory they certainly afford very favourable evidence on behalf of the treatment of popliteal aneurysm by ligature of the superficial femoral artery. Among 43 cases there was no death, although four patients were submitted to amputation for gangrene or ulceration. In 34 cases there was uncomplicated recovery, whilst in 5 subsequent treatment was required for recurrent pulsation, the operation in 3 of these having been preceded by a trial of digital compression. The evidence seems, therefore, to support the view that in the majority of cases of popliteal aneurysm it is wise to ligature the superficial femoral artery without resorting to digital compression before the operations. Further experience will probably show that the best available operative treatment for recurrent pulsation is excision of the sac. I may mention that in the published reports of the three hospitals mentioned above I can find only one case in which the popliteal artery was ligatured as a first means of treatment and that the result was successful.

I am, Sirs, yours faithfully,

Weymouth-street, March 4th, 1897. RAYMOND JOHNSON.

"LUXATION OF A SESAMOID BONE OF THE GREAT TOE."

To the Editors of THE LANCET.

SIRS,—Is it not possible that the displaced sesamoid bone referred to in your annotation on Mr. Thorburn's case [1] had nothing to do with the symptoms? In most skiagraphs of the foot that I have seen this bone is apparently luxated or subluxated outwards. Probably this is due to the average boot, which displaces the phalanx, which in its turn carries with it the flexor tendons and the sesamoid bones. The condition is, I suspect, an universal accompaniment of hallux valgus, and the displacement varies with the amount of the deformity. I enclose a print which well shows the shadow of the sesamoids, the outer one being almost clear of the outer margin of the metatarsal bone, and the inner one showing as an increased shadow under the head of that bone. The skiagraph in question was taken to locate a needle in the foot. The valgus deformity was not well marked. This patient suffered no inconvenience from the needle or the "luxation of the sesamoid bone." I may add that the Crookes's tube was placed over the middle of the foot, so that the shadow is rather displaced inwards than outwards. In another case where the tube was placed internally to the inner border of the foot the displaced bone also shows clearly. I am, Sirs, yours faithfully,

Seymour-street, W. E. MUIRHEAD LITTLE.

*** Mr. Little encloses a skiagraph which shows well the displacement referred to.

THE HEALTH OF THE ARMY IN INDIA.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 6th you give my name as a member of a committee, appointed by a meeting held at the United Service Institution on Feb. 27th, to obtain the protection of Her Majesty's forces in India from contagious diseases. Allow me to state that I was not at the meeting and have not joined the committee, of which, indeed, I know nothing except from this statement.

I am, Sirs, yours faithfully,

J. F. PAYNE, M.D. Oxon.

Wimpole-street, Cavendish-square, W., March 8th, 1897.

[1] THE LANCET, Feb. 6th, 1897.

"INSUSCEPTIBILITY TO VACCINATION."

To the Editors of THE LANCET.

SIRS,—In the supplement to the *Scientific American*, dated Dec. 26th, 1896, there is an article from THE LANCET on "Insusceptibility to Vaccination," which concludes with these words: "Although insusceptibility is admitted by law it really becomes doubtful whether it has more than a legalised existence." That insusceptibility exists I am convinced, for I have vaccinated one of my daughters with lymph from arm to arm at least fifty times, and brother practitioners have also vaccinated her as many times more (in most cases with perfectly fresh lymph from arm to arm) between the years 1873 and 1895, and always unsuccessfully. This, it is true, is but one case, but it is sufficient to prove that insusceptibility exists. I am, Sirs, yours truly,

Iquique, Chile, Jan. 22nd, 1897. J. W. MERRIAM, M.D.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

To the Editors of THE LANCET.

SIRS,—The next annual meeting of this association will be held in Newcastle, at the College of Medicine, in the latter part of July. Notice of the dates and other particulars will be issued in due course. A considerable part of the time of the meeting will be devoted to discussions, papers, and demonstrations on subjects connected with Insanity and the Structure and Functions of the Brain and Nervous System. It is hoped that a large gathering of members will be present to show their interest in the work of the association, to read papers, and take part in the discussions. It is desired to provide a programme worthy of the association and of the wide field of scientific and social subjects with which the association is concerned. We desire to incorporate as large a portion as possible of the programme in the next circular and shall be glad to receive at an early date the title of the paper which any member proposes to read at the meeting or subject he designs to bring before it.

We are, Sirs, faithfully yours,

T. W. MCDOWALL, M.D. Edin.,
President-elect,
Northumberland County Asylum, Morpeth;
R. PERCY SMITH, M.D. Lond.,
Hon. General Secretary.

11, Chandos-street, Cavendish-square, London, W.,
March 10th, 1897.

"CORONER AND MEDICAL MAN."

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Snell's question, a coroner can issue no *order for burial* unless he holds an inquest. It frequently happens that cases are submitted to the coroner by the registrar, medical men, and others for his judgment as to whether an inquest should be held or not, and in these cases, when he considers an inquest unnecessary, he fills up a form supplied by the registrar. This is not an *order* for burial, but merely a statement that the coroner does not intend to hold an inquest, and although the alleged cause of death may be entered the death is registered as uncertified. Supposing no certificate of the cause of death is obtained from a duly qualified medical practitioner, ignorant people often consider the form used by the coroner in declining an inquest to be a *burial order*, but it is not so.

I am, Sirs, yours faithfully,

March 6th, 1897. M.B.

THE CHOICE OF AN ANTISEPTIC IN MIDWIFERY.

To the Editors of THE LANCET.

SIRS,—Can you kindly, through the medium of your valuable journal, give me the following information, for which

Hosted by Google

I shall feel greatly obliged to you:—1. Has perchloride of mercury been absolutely demonstrated beyond doubt a more reliable antiseptic than carbolic acid in confinements? 2. Is biniodide of mercury as powerful and reliable an antiseptic as the perchloride, and is it less liable to cause mercurialism?

I have always used carbolic (1 in 40 to start with) for uterine irrigation with the best results. On one occasion only I used perchloride (a case of puerperal septicæmia), but after two or three days, there being no improvement, I changed to carbolic, and the temperature dropped at once. I am loth to give up what I have learned to trust and what has never failed me, but carbolic has been discarded in so many quarters that I feel doubtful if I am doing right in not changing. As regards mercury biniodide, I have seen it stated that it is as powerful an antiseptic as the perchloride and much less poisonous. Is this a fact? If so, why is it not used in preference for midwifery practice?

I am, Sirs, yours faithfully,

Feb. 22nd, 1897. ANTISEPTIC.

Our correspondent is referred to an Annotation in our present issue.—ED. L.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Ophthalmic Diseases at the Kirkdale Industrial Schools.

THE report of the Local Government Board inspector to his department on the unhealthy condition of the children's eyes at the Kirkdale Industrial Schools appears to indicate an unsatisfactory state of things. Out of 136 girls at the schools he found 45 suffering from granular lids, and 8 out of this number presented a severe form of the disease. Of 335 boys, 91 suffered from granular lids. In the nursery there were 45 children, 28 of whom were in a similar condition in a more or less infective form. One of the attendants, aged twenty years, was also suffering. Of 54 children in the infirmary 19 had the disease. It would thus be seen that 33 per cent. of the girls, 27 per cent. of the boys, 62 per cent. of the nursery children, and 33 per cent. of the infirmary inmates were suffering from granular lids in a more or less infective form. In looking through the medical officer's (Dr. McMurray) report book he found the term "preventive" used in relation to the course of treatment. Dr. McMurray explained that he could not say the treatment was curative; his object was to pick out cases of granular lids that were, in his opinion, in an infective condition, isolate and treat them for a fortnight or three weeks, and return them to the schools if he thought all risk of infection had passed away for the time being. From what he (the medical inspector) could see of the cases there was no doubt that Dr. McMurray was to a certain extent successful in his endeavour, but it could be easily understood how, if sixty or eighty children, a certain proportion in a chronic quiescent state, were drafted from Kirkdale to a certified home such as Layfield, the children might become active sources of infection. Dr. McMurray quite concurred with this view, and said that if he had facilities for isolation for a large number of boys and girls he would be able to treat adequately all cases of granular lids at present in the schools, and in two or three years could stamp out the disease. It seemed to be necessary that, under existing circumstances at Kirkdale schools the medical officer should be requested to make weekly examinations of the eyes of all the children so as to detect the first onset of sub-acute symptoms and at once place the children under treatment. The chairman of the select vestry thought that matters should not be prejudged until their medical officer was first allowed an opportunity of explaining. Subsequently at a meeting of the committee of the industrial schools Dr. McMurray furnished a report in which he refuted the allegations made by the Local Government Board inspector, as to the alarming presence of eye diseases among the children in the schools. The committee resolved to forward Dr. McMurray's report to the Local Government Board. The chairman was of opinion that the inspector's report was exaggerated, which was endorsed by other members of the committee, who expressed confidence in their medical officer. The inspector had also reflected on the condition and the treatment of some children's eyes in the Liverpool Workhouse—charges which were repudiated in forcible language by Dr. Alexander, the visiting surgeon. An ophthalmic surgeon would be of service here to give his opinion on the whole matter.

The Head Constable's Annual Report.

The head constable, in his annual report for 1866 to the watch committee, says that a great and steady improvement in the condition of the city as regards crime and disorder is disclosed. The decrease in intemperance has continued, and it is stated that there is now considerably less than one-third of the drunkenness that there was eight years ago. Proceedings against keepers of disorderly houses were taken in 139 fewer cases than in 1895, in 299 fewer than in 1894, and 456 fewer than in 1893. The head constable adds that the number of women of bad character in the city has not decreased in like ratio, if at all, and the facts mentioned last year still hold good. The table relating to the number of accidents reported by the police includes 159 cases of attempted suicide, of which 41 proved fatal; 151 individuals were bitten by dogs; 60 people fell from buildings, 5 of whom were fatally injured; and 444 individuals were run over by carts, &c., 20 deaths resulting. Burns, of which 66 cases were reported, accounted for 17 deaths. The total number of accidents reported by the police amounted to 3479, of which 188 proved fatal. Assistance was rendered by the police in 2861 cases as follows: Applying bandages in 91 cases; stopping bleeding, 29; administering emetics, 16; other assistance, 401; taken to hospitals, &c., for treatment (no first aid being rendered), 2295. Of the total number of apprehensions of drunk and disorderly persons, which amounted to 6146, there were 11 representatives of the "law, medical, and other professions." Let us hope that there was only one medical man of this number.

Liverpool Medical Club.

At a meeting of the members of the Liverpool Medicae Club, held on Feb. 17th, Mr. E. W. Barnes introduced thd subject of the Abuse of Medical Charity. He mentioned the various medical charities which were chiefly affecteh and clearly pointed out the main causes and effect of suce abuse. He estimated that about half-a-dozen only of the public medical charities in Liverpool (not including the Poor-law, which he did not consider abused) supplied something like 400,000 attendances annually out of a population of 644,129. The remedies he advocated were: (1) the formation of local hospital boards; (2) catering for the intermediate class of patient; and (3) the formation of local committees under the auspices of the Hospital Reform Association. After an exhaustive discussion, a resolution was unanimously carried "that the directors of the club be empowered to form a local committee of inquiry to report upon the matter as the first step."

The Tuberculin Test at St. Helens.

Dr. Robertson, the medical officer of health of St. Helens, recently demonstrated to the farmers of the neighbourhood by means of the tuberculin test that a heifer to all appearances perfectly healthy and in good condition may nevertheless be the subject of tubercle. For some time past the majority of the butchers of St. Helens declined to attend the local stock sales unless the auctioneers were empowered to give a guarantee against the presence of tuberculosis in the beasts sold. Hitherto a guarantee to this effect had been refused by the farmers; however, one of their number said that he would guarantee a three-year-old Ayrshire heifer. This gentleman had previously submitted five of his beasts to the tuberculin test, and although the test showed the beast to be affected when slaughtered two of them proved to be healthy. Upon hearing this statement the farmers were naturally inclined to discredit the tuberculin test. Dr. Robertson, when communicated with upon the subject, said that he could not believe that the test had failed; whereupon the same farmer again submitted one of the five beasts to Dr. Robertson and Mr. Dixon, veterinary surgeon. The beast, which was apparently in first-class health, again "reacted" under the test, and was declared by Dr. Robertson to be suffering from tuberculosis. The farmer, still unconvinced, said he would guarantee the beast at the approaching sale on condition that it was taken straight to the abattoir and slaughtered, which was accordingly done. The carcase proved generally healthy, but upon the lungs being examined one of them was found to be affected with chronic, though dormant, tuberculosis, the glands being also enlarged; whereupon the butcher who bought the beast was at once absolved from his bargain

Hosted by Google

under the terms of the guarantee. The farmers present were greatly surprised to find so healthy-looking a beast affected.
March 9th.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Bristol General Hospital.

THE half-yearly general meeting of the governors of this institution was held on March 8th, under the presidency of the Mayor. The annual report which was read stated that the appeal made for the Nurses' Home had resulted in the sum of £3237 being raised; this had been sufficient to discharge all liabilities incurred for building and furniture, but £350 had still to be raised to cover the cost of the houses which were pulled down for the purpose of the enlargement. The home is now finished and proves of great utility to the hospital. Exclusive of the special fund for the Nurses' Home, the total ordinary receipts are £9600, or less by £562 than those of 1895. The total ordinary expenditure (£10,633) is somewhat less than in 1895 owing to the smaller amount spent in repairs. This amount is much beyond the ordinary income, and the committee do not see how it can be reduced without impairing the efficiency of the hospital. The committee thank the honorary staff and the resident medical officers for the admirable way the work of the hospital has been carried on during the year. The daily average number of in-patients has been 171·6. The in-patients treated during the year were 2333, and the out-patients numbered 30,166, the totals for the year of both having slightly increased. Since the hospital had been established in 1832 there had been admitted 71,721 in-patients and 682,499 out-patients.

The Bristol Medical School.

The following scholarships have been awarded:—The Clarke Surgical Scholarship of £15 was equally divided between Mr. E. V. Foss and Mr. R. F. Moorshead. The Sanders Scholarship of £22 10*s.* was awarded to Mr. F. P. Mackie, and the Lady Haberfield Prize of £29 9*s.* 8*d.* to Mr. A. G. Plumley. The Martyn Memorial Pathological Scholarships were divided as follows: Mr. F. P. Mackie, £10; Mr. W. M. Bergin, £5; and Mr. H. L. Norrington, £5. The committee gold medal was gained by Mr. W. M. Bergin, and the silver medal by Mr. F. Rose.

Dr. Nansen.

Dr. and Mrs. Nansen arrived at Cardiff on Feb. 28th, and were received by Mr. Drane (president of the Cardiff Naturalists' Society), Dr. Charles Vachell, and others. Dr. Nansen delivered his lecture in the Park Hall the same evening, the building being filled to its utmost capacity. On March 1st Dr. Nansen gave a lecture in Bristol on his Arctic exploration and received an enthusiastic welcome. Professor Lloyd Morgan introduced the lecturer. Dr. and Mrs. Nansen were the guests of Mr. W. Sturge while in Bristol.

Public Health Department for Cardiff.

At a meeting of committees of the Glamorganshire County Council, held on March 5th, the question of providing a public health department in connexion with the University College of South Wales and Monmouthshire, and the provision of a laboratory for the county medical officers, was discussed. It was decided to recommend the council to subscribe £2000 towards a private laboratory and a department for the county medical officers in connexion with the new college buildings. The details were left to be dealt with by the sanitary committee of the Glamorganshire County Council.

A New Hospital for Cardiff.

At a meeting held on Feb. 24th at Cardiff it was decided to raise a fund for the purpose of erecting, as a memento of Her Majesty's reign, a permanent seamen's hospital for the port of Cardiff in place of the *Hamadryad* hospital ship. The Marquis of Bute has offered to subscribe £5000 and present a suitable site, provided that at least £30,000 were raised by subscriptions. Mr. Cory will give £1000, and other donations are promised.

Rabies and Anthrax.

At the quarterly meeting of the sanitary committee of the Glamorganshire County Council, held last week, the chairman reported that an outbreak of rabies had occurred in Monmouthshire. The inspectors were instructed to secure all stray dogs and to kill them if they were not claimed. Dr. Williams, the medical officer for the county, reported that an outbreak of anthrax had occurred in several districts, and recommended that in future carcases should be cremated instead of buried.

Successful County Court Action by a Bath Surgeon.

At a special sitting of the Bath county court, held on March 1st, Mr. R. J. H. Scott, F.R.C.S. Edin., surgeon to the Royal United Hospital, brought an action against a firm of Bristol brewers for personal injuries and damage to a brougham alleged to have been caused through the negligent driving of a drayman in the employment of the defendants. The charge was fully borne out by plaintiff and a number of witnesses. Mr. Scott obtained a verdict for £14 18*s.*

Aberystwith University College.

The council of Aberystwith University College has decided to spend £15,000 in finishing the erection of a new wing to the college buildings.

The Bridgwater Infirmary.

The heavy gale experienced in the West of England on March 3rd injured the Bridgwater Infirmary. Two chimneys were blown down and the débris broke through the roof and ceiling of the male wards. Fortunately the patients were unhurt. The furniture of the wards was much injured. The patients were removed to another ward. The damage done to the infirmary premises is very considerable.

Neglect of Vaccination at Swindon.

At the last meeting of the Swindon Board of Guardians the vaccination officer reported that in 1895 there were 1352 births, and of these children 319 were successfully vaccinated, 104 died unvaccinated, 600 remained unvaccinated at the present time, and the others had removed to other districts. For the first six months of 1896 the number of births was 650, of which 139 were successfully vaccinated, 70 died, 300 were still unvaccinated, and others were removed to other districts or were postponed. No action was taken upon the report.

A New Technical Institute for Bradford-on-Avon.

On Feb. 24th a new technical institute, erected at a cost of £3600 at Bradford-on-Avon, was opened by Professor Michael Foster of Cambridge University. Very handsome contributions have been given, including £1000 from the Wilts County Council and £1000 from Lord E. Fitzmaurice.

The authorities of the Newport Metal Exchange have voted 50 guineas to the new infirmary at Newport (Mon.).
March 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow Medico-Chirurgical Society.

AT a meeting of this society held on the 5th inst. Mr. R. H. Parry demonstrated a number of specimens of gynæcological interest. The specimens included several Fibroid Tumours of the Uterus removed by abdominal section, a number of the cases being complicated by pathological conditions of the ovaries and Fallopian tubes; the Uterus and Appendages removed *per vaginam* for an obstinate and long-continued chronic metritis; and a Tubal Pregnancy in the second month of gestation with the ovum *in situ* removed by abdominal section. There was in the last case a feature of special interest, inasmuch as the patient when seen by her medical attendant was regarded as suffering from retroversion of the uterus, and an attempt to forcibly replace the organ was followed by peritonitis. It was only on the subsidence of this condition that the tumour was discovered and a diagnosis of extra-uterine pregnancy made. Mr. Parry also showed a Segment of the Small Intestine resected for chronic obstruction due to stenosis of the gut, the result, it was suggested, of cicatrised tuberculous ulceration; and a Scapula with its Muscular Coverings removed in consequence of the growth of an adherent parosteal sarcoma. The demonstration was completed by the exhibition of a patient, a man who had been obliged to give up his work as a boiler-maker in consequence of the development of Spasmodic Torticollis. The head had been turned strongly to the left

Hosted by Google

side and the chin markedly elevated. This condition persisted even after resection of the right spinal accessory nerve. The suggestion then arose that the muscles at fault were probably the post-occipital muscles on the left side, and it was determined to divide the posterior primary divisions of the upper cervical nerves. This operation was carried out and had proved quite successful, the patient having been for upwards of a year quite free from any distortion of the head. The President (Dr. W. L. Reid), on behalf of the members, thanked Mr. Parry for his interesting demonstration.

Glasgow Southern Medical Society.

Professor McCall Anderson received the members of this society in his wards in the Western Infirmary on the evening of the 4th inst., when he gave a most instructive clinical demonstration. The patients shown included cases of Cerebral Tumour, Disseminated Sclerosis, Progressive Muscular Atrophy, Exophthalmic Goitre, Thoracic Aneurysm, and Molluscum Contagiosum. In addition Professor Anderson demonstrated a case of word-blindness with right lateral homonymous hemianopia, and several patients who had been treated by injections of tuberculin, with others in whom anti-syphilitic serum had been used. Various photographs illustrating the value of the Roentgen rays were shown, and also a specimen of urine containing hæmato-porphyrin. The demonstration was a decided success and was highly appreciated by a large audience.

Lecture by Professor McKendrick.

The fifth lecture of the series of free Monday lectures by the professors of the University of Glasgow was delivered by Professor McKendrick on the 8th inst., the subject being Sound Waves as Revealed by the Phonograph. After reference to the physical causes of pitch, intensity, and quality of sound, Professor McKendrick described an instrument called the phonograph recorder, by which curves corresponding to the marks of the wax cylinder of the phonograph are written upon a piece of paper. In this way curves may be obtained and analysed and the various partial tones which exist in a compound tone can be distinguished and appreciated. Professor McKendrick also showed a method he has devised for communicating sound vibrations to the deaf and dumb, and demonstrated this on several deaf mutes, who by beating time with their hands showed they were sensible of the rhythm of a piece of music. The lecture commanded a large audience, which included Lord and Lady Kelvin.

March 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Kingstown.

THE chairman of the Kingstown Commissioners, Mr. A. S. Findlater, J.P., at the monthly meeting of the Board of Commissioners on the 2nd inst. drew attention to the sanitary state of the township and read the report of the superintendent medical officer of health on the condition of Kingstown during the four weeks preceding the beginning of last month. The returns showed that the number of deaths represented an annual death-rate of only 20·3 per 1000. The rate in the twenty-three principal towns of Ireland for the same period was 32·5, 45·3 in Dublin, 20·9 in Rathmines, 23·6 in Blackrock, and 18·6 in London.

Ulster Medical Society.

The March monthly meeting of the Ulster Medical Society was held on the 4th ult. in the Pathological Laboratory of Queen's College, Belfast, when a series of most interesting demonstrations were given with microscopic and other preparations. The President (Professor Symington) and Dr. Smyth showed specimens of the Central Nervous System stained by Weigert's method; the President and Dr. R. J. Johnstone showed specimens illustrating Cranio-cerebral Topography; Dr. Tennent read a paper on the Structure of Uterine Fibroids, illustrated with a series of microscopic sections; Dr. Lynass gave an account of Unna's Classification of Epitheliomata of the Skin, with illustrative sections; Dr. Lynass, Surgeon-Major Bigger, Dr. Donnan, and Dr. Colville demonstrated Widal's Serum Method of Diagnosing Typhoid Fever; Surgeon-Major Pike read notes of (*a*) a case of Injury to the Neck of the Femur, with skiagraph; and (*b*) Severe Secondary Syphilis complicated with Diphtheria in the primary stage, with photograph; Dr. Cecil Shaw showed a New Bacillus isolated from a case of Tonsillitis; and Dr. Osborne showed a series of Physiological Microscopic Specimens. In the discussion which followed the papers Professor Byers, Dr. M'Keown, Dr. John Campbell, Dr. L. Smith, Dr. Walton Browne, Professor Thompson, and Dr. Fielden took part. Lord Lister was elected an honorary member of the society.

The Hospital for Infectious Diseases, Belfast.

At a meeting of the public health committee held on March 4th, the question of the plans for the new hospital for infectious disease was under consideration, when a motion to adjourn the subject until after the election of the new council in November was carried. The question of a new infectious diseases hospital is therefore postponed, and as a consequence it will not be possible to work properly the Infectious Diseases Notification Act, which has just come into operation.

The Union Workhouse, Belfast.

In his half-yearly report, just published, Mr. Agnew, Local Government Board inspector, says that the operating room was very unsuitable, and he thought the nurses' room could be easily utilised for that purpose. He thought the water-supply was neither sufficient nor wholesome. The wards of the workhouse and infirmary were not properly ventilated, and the lavatory and bathing accommodation on the healthy side of the house was unsuitable. Separate wards have not been provided for phthisical and erysipelas patients, as suggested in his last report, and there was no isolation ward for cancer cases. There were 1140 patients in the infirmary on the date of his visit under the charge of three resident and two visiting medical officers. The night nurses were insufficient, as several of them had 150 patients. There were on the day of his inspection in a separate and detached building, at a cost of £16,000, 418 classed as lunatics, 172 males and 246 females. The accommodation for these was, Mr. Agnew reports, ample and suitable and superior to any he had seen in Ireland. In the fever hospital the nursing staff was highly efficient and the medical staff admirably suited for the treatment of infectious diseases. The beds were comfortable, the clothing clean, and the patients well attended to.

Armagh Lunatic Asylum.

The urgent necessity of providing additional accommodation at the Armagh Asylum has been met by the erection, upon an elevated plateau within the asylum grounds, of a detached hospital (following the type found to be so successful in Scotland), planned to accommodate 150 patients under special treatment, together with the necessary attendants and staff. The building is almost complete, the only things to be done being the finishing of the electric installation and the furnishing of the wards. Indeed, owing to the overcrowding of the asylum, certain dormitories in the buildings have had to be occupied almost as soon as they were built. This detached hospital is the first of its kind in Ireland, and in its wards all the acute and recent cases requiring observation, as well as the bodily sick and other inmates who require specific medical care, will be brought together. The ventilation, building, and sanitary arrangements are all of the most recent and complete planning and construction; and this new detached hospital will be of the greatest utility as an addition to the Armagh Asylum.

The Battle of the Clubs at Cork.

Some few weeks ago Mr. Philip Lee received permission at a meeting of the profession to form a new club consisting of such members of the clubs he formerly held as may decide on joining together to form the club. Already fifty members have entered their names, and that is a large number considering the fact that none having incomes of £100 a year are eligible for membership. It is expected that others of the medical men who held clubs will seek for similar permission, and in that way there will be, it is hoped, several successful invasions of "Club-land."

Ladies as Poor-law Guardians.

At Tralee, Killarney, and Fermoy severally there are two ladies aspiring for the position of poor-law guardian. Opinion in the neighbourhoods is divided upon the advisability of employing the services of a lady, but it is generally felt that in workhouses and union hospitals there is a field for work that should properly fall to the gentler sex.

Hydrophobia.

A young girl died from hydrophobia in the Skibbereen

Hosted by Google

Workhouse Hospital last week. The disease is stated to have developed only two days previously, and the bite had been inflicted six or seven weeks prior to her illness.

Appointments.

Mr. W. H. Langley has been appointed medical attendant to the Ordnance Survey Barrack, Phœnix Park, and to the Morgan School, Castleknock, in room of the late Mr. R. F. Maguire, deceased. Mr. Joseph J. Cullen of Dalkey has been elected to the office of dispensary medical officer for the Castleknock district.

March 10th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Academy of Medicine and the Manufacture of Matches.

AN important discussion has occupied the time of many sessions of the Academy as to the hygienic conditions which it is desirable to impose upon the manufacture of matches. In France the manufacture of matches is a State monopoly and under State control, and in view of the numerous cases of illness among the workers and the many complaints which have been made in the press the Minister in charge has asked the Academy of Medicine to draw up rules for the regulation of the Government factories. Current opinion in the Academy was divided. One party advised that white phosphorus should no longer be used in the manufacture of matches, saying, also, that this advice was what the Minister really needed to satisfy the press and that the opinion of the Academy had been asked for in order to use it as a lever to obtain from the Chamber the supplies necessary for the complete transformation of the match industry throughout France. In Belgium it was noted that when the same reform was demanded, the workmen and manufacturers alike asked that, if the use of white phosphorus was forbidden in Belgium, its use should at least be allowed in the manufacture of matches intended for foreign countries, as its suppression would ruin the factories possessing the necessary plant, and bring great poverty upon the workmen thrown out of work. Others in the Academy, however, thought with M. Magitot and M. Bouchardot that it would be quite sufficient from a sanitary point of view to alter the arrangement of the workshops so as to obtain thorough ventilation, while refusing work to all who had not good teeth. The workers must be under strict medical supervision, and as far as possible machinery should be constructed so as to allow the whole process of manufacture to go on under glass, the workmen being protected from the poisonous fumes. In two factories—namely, at Algiers and Aix—there has not been a single case of phosphorus poisoning for twelve years, owing to the strict hygienic rules which have been in force. The cases which have so excited public opinion occurred at Aubervilliers, a suburb of Paris, in a very old factory, which it is impossible to put into a sanitary condition and which ought to be pulled down, as to make it really healthy would cost more money than to build a new one. The real fact is that the workmen of Paris object to the introduction of machinery for the safe manufacture of matches with white phosphorus—that is to say, under glass—for in that case far fewer hands would be wanted, and they therefore demand the use of red phosphorus, to work in which necessitates a larger staff. This is the reason why in Belgium, where the manufacture of matches is free to anyone, the workmen object to red phosphorus, and why, in France, the State, which panders to the political influence of the workers, is ready to satisfy them on this question, despite the increased expense. Matches made with red phosphorus are not so good as the others, for they are more difficult to light, the wood is very brittle and often breaks, and the composition for tipping them demands the use of explosive materials which, like poisoning, constitute a serious source of danger. The Academy has agreed to the following answer being sent to the Minister:—1. It is necessary to put a stop to the unhealthy conditions which exist in many of the match factories in France. 2. The suppression of the use of white phosphorus is the only certain way of insuring health to the workers in this manufacture. 3. The employment of perfected automatic machinery is a costly matter and carries with it the condition that all dangerous operations should be done under glass. 4. Until these recommendations can be carried out as a whole the present unhealthiness can be diminished by thorough ventilation, short shifts for those men working in the dangerous shops, careful selection of healthy hands, and periodical medical inspection, with power to prohibit the labour, either for a time or altogether, of anyone with lesions of the mouth or whose general health is impaired. There should also be better provisions provided at the factories and more rigorous inspection of eating-rooms, lavatories, cloak-rooms, &c.

Medical Matters and the Army.

The scarcity of army surgeons continues to be the subject of discussion in the army and the press. Resignations become more and more frequent owing to the dissatisfaction of the military surgeons, who complain that promotion is too slow, that they are the object of less consideration than other officers, and that they have to submit to frequent injustice through being attacked in the press and not supported by the War Minister. A resignation which has created great excitement has just taken place—namely, that of M. Laveran, ex-professor of the School of Military Hygiene, a member of the Academy of Medicine, and well known for his discovery of the hæmatozoon of malaria. The professors are nominated for ten years only, and at the expiration of M. Laveran's term his post was changed and he was sent by the War Minister to a provincial garrison town as a simple army surgeon, no regard being paid to his position as a member of the Academy or to his great scientific reputation. He remained for some time at this station with a rank far below that to which his length of service entitled him, coming to Paris and continuing his researches at the Academy. In consequence of the delays and worries which the War Department made him undergo, putting actual obstacles in the way of his scientific work, he preferred to send in his resignation and to quit the Army Medical Department, of which he had been a prominent figure, at the age of fifty-six years. Everywhere an increase in the number of army medical men is demanded, and in certain army corps where the regiments have been increased by a battalion the number of medical officers remains the same. At Epinal there is a regiment of infantry in which the men of one battalion have to go five kilometres to see the surgeon of the regiment, who is in sole charge of two battalions. The War Minister has just authorised privates and officers to join the Temperance Society (Société contre l'Usage des Boissons Spiritueuses). This is a remarkable thing, for in France soldiers are not allowed to join any society, even a charitable one.

The Surgical Society.

La Société de Chirurgie is at present discussing the operative treatment of exophthalmic goitre, and the members are bringing forward their cases of operation, successful or otherwise. M. Lejars reported a case of sudden death on the day of operation not to be explained by hæmorrhage or any other lesion. M. Schwartz reported a case of complete cure of all the symptoms associated with Basedow's disease, the tumour removed being of small size. M. Tuffier had operated twice. In one case he had removed, only the right lobe and the cure was complete; in the other he had also performed a partial removal, and though there was great amelioration of the symptoms, yet the exophthalmos persisted. M. Poncet attributed the accidents which sometimes followed these operations to an intoxication owing to the thyroid secretion having poisoned the wound, giving rise to an acute attack of "Basedowism." M. Poncet considered that the greatest precaution should be used with regard to surgical interference in these cases, and advised division of the large sympathetic nerve on both sides with removal of the superior cervical ganglion in preference to interfering with the thyroid gland. By this method he considered relapses would be avoided such as often occur with thyroidectomy.

March 9th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Bacillus of Plague.

A PAPER on the bacillus of plague was recently read before the Berlin Medical Society by Dr. Kolle, assistant to Professor Koch, and the substance of it has been published in the *Deutsche Medicinische Wochenschrift*. The microscopical examination of pus obtained from typical cases of

Hosted by Google

plague shows leucocytes, detritus, red corpuscles, and an enormous mass of bacilli, which are small, have spherical extremities, and are quite different from all the other pathogenic bacilli; when they are stained their extremities become intensely coloured, whilst the middle remains colourless. The only organism which can be confounded with the bacillus of plague is the bacillus of fowl cholera—a disease quite harmless to human beings; the bacillus of fowl cholera, however, is the larger of the two. The bacillus of plague is found in the glands, the spleen, and the blood. Plague must thus be regarded as a specific polyadenitis, which finally leads to specific septicæmia. In grave cases streptococci were, moreover, discovered by Dr. Aoyama. The presence of these streptococci is due to a secondary infection, just as in the case of scarlet fever, enteric fever, &c. They are found especially in the last stage of the disease and are easily distinguished by Gram's method, the plague bacillus remaining colourless whilst the streptococci become stained. The bacilli of plague can be cultivated by the usual methods. On agar the colonies begin to appear twenty-four hours after the inoculation; they at first look like small drops; after forty-eight hours they have the form of grey opalescent buttons. They do not liquefy gelatin. They can also be grown on potatoes and on blood serum, and in the cultures obtained in this way the morphology of the bacilli may be easily examined. They are usually short, not motile, and not provided with flagella; the presence of a capsule is still doubtful. The size is not very constant; sometimes they are very short, sometimes they are longer or have a diplococcus-like structure. A spheroidal form is a symptom of degeneration and is never found in fresh cultures, but only in old ones. Spores were never discovered. Kitasato and Yersin have stated that the cultures are destroyed in a few hours by a temperature of 58° C. and in a few minutes by a temperature of 100° C.; the usual chemical disinfectants destroy them very soon. Dr. Kolle employed four cultures for the purpose of his researches. The first was obtained from a case which occurred during the Hong-Kong epidemic in 1890, the second was placed at his disposal by Dr. Metchnikoff of Paris, the third by Dr. Macfadyen of the British Institute of Preventive Medicine, and the fourth by M. Haffkine of Bombay. In all these four cultures, coming from different sources, the bacilli proved to be identical; but there was, however, a great difference in their virulence. According to Kitasato and Yersin the virulence of the bacilli of plague may be easily studied in rats, mice, and guinea-pigs, which are very liable to be infected, and with this Dr. Kolle fully agrees. If only a small quantity of a fresh culture is inoculated through the skin of one of these animals it dies within a few days, and after death the bacilli are found in great quantity in the blood, the internal organs, and also in the neighbourhood of the wound. After an intra-peritoneal or intra-vascular injection death occurs much sooner—sometimes in a few hours. Injections of less virulent cultures give rise to symptoms very like those observed in the human subject. After four or five days the lymphatic glands gradually begin to swell, the animals lose their appetite, become very weak, and then die—as a rule within the second week. After death the glands are found to be inflamed and studded with hæmorrhages, while in the centre there is a deposit of pus. Rats and mice may also be infected either by mixing a culture of the bacilli with their food, in which case the mesenteric glands are the most swollen, or the disease may be communicated to the animals by inhalations. It is thus proved by these experiments that rats and mice may easily spread the disease, a fact in accordance with the observations of Yersin during the recent epidemic and also confirmatory of the historical accounts which state that during mediæval and subsequent epidemics these animals caught the disease prior to man. The infected rats and mice are a source of great danger to the public owing to their excrement being deposited in dwelling-houses. Experiments in laboratories must therefore be performed under every possible safeguard, and precautions must be taken to prevent infected animals escaping. With respect to the method of infection in man Yersin, Kitasato, and Aoyama have during the recent epidemic observed that the disease may originate from peripheral infection—namely, from inoculation of the bacilli through the skin. This may happen in different ways, as, for instance, through wounds, caused either by splinters or by bugs, fleas, or other insects. Yersin has discovered bacilli in the mud of houses where plague patients had lived. He has, also, made valuable experiments as to the possibility of immunisation. He injected horses with increasing doses of fresh agar cultures, and found that if 0·1 c.c. of their blood serum obtained three weeks after the last injection were injected into mice twelve hours before inoculation with a culture of the bacilli of plague the animals remained immune. By an injection of from 1 to 2 c.c. of this serum twelve hours after the administration of a virulent culture the life of the animals could be saved. The serum was used in Hong-Kong for twenty-six patients, of whom only two died; this is a mortality of no more than 7·6 per cent., whereas the ordinary mortality from plague is 90 per cent. Experiments on immunisation have also been made by Dr. Kolle, but he is not yet prepared to publish his results.

Sterilisation of Water by Bromine.

Dr. Schumburg, chemist to the Army Medical Academy, has published in the *Deutsche Medicinische Wochenschrift* a method of rendering unwholesome water fit for drinking by the use of certain chemical agents. He says that, whilst the methods of filtering river water employed by public bodies give as a rule very good results, the domestic filtration by means of portable filters, as used in country places, is far from being satisfactory. In the course of numerous experiments he has discovered that a solution of bromine destroys all the pathogenic germs in water. When a quantity of ammonia is then added the water becomes clear and palatable; 0·2 grammes of a solution of 20 grammes of bromine and 20 grammes of bromide of potassium in 100 grammes of water will sterilise a litre of water from the River Spree. To remove the bromine a definite quantity of a 9 per cent. solution of ammonia is added. This discovery was the outcome of 200 experiments performed by Dr. Schumburg with water to which there had been added bacilli of cholera and enteric fever as well as other dejecta and a great number of saprophytes of almost every kind. Dr. Schumburg appropriately points out that a simple method of sterilising water which has to be used for drinking purposes may be very important, either on a campaign or at sea, or during the prevalence of an epidemic.

March 4th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Autumn Manœuvres and the Red Cross.

THIS year, in the latter half of September, the "grandi manovre" will take place in the tract of country lying between the Adige and the Chiese, affluents of the Po—a tract in great part corresponding to the famous Quadrilateral, bounded by Peschiera on the north-west, by Verona on the north-east, by Legnago on the south-east, and by Mantua on the south-west. The Red Cross societies will, as usual, be represented at these manœuvres, not, however, in certain details which have been conspicuous of late years. In Piedmont, for instance, and Tuscany the mountain ambulance was a prominent feature in recent Red Cross intervention, but it will not be so certainly next September. An opportunity, on the other hand, is presented for mobilising that "Red Cross afloat," on which THE LANCET has from time to time commented. The scene of the coming manœuvres is, to say nothing of canals, rich in natural water-way—from the Lago di Garda on the north to the great artery of the Po to the south, with the intervening Chiese and Adige west and east. Italy is, I believe, unique in having a Red Cross service afloat, and her resources in this direction—if, as is more than probable, they are to be put *en évidence*—will add another to the attractions which the yearly manœuvres of her army possess for the military world.

The Government and the Appeal to the Country.

In view of the general elections, which will begin on the 21st inst., the Di Rudini Administration has issued a manifesto setting forth its political programme, domestic and foreign. It is an able document, and is already being eagerly analysed, combated, and defended by the various divisions of party. Surprise, however, is expressed, not by the Opposition only, that it ignores hygienic reform entirely. This is the more unaccountable as the Marchese di Rudini has shown a practical appreciation of Italy's backwardness in matters of public health. From his predecessors, moreover, notably from the Crispi Administration, he has

Hosted by Google

inherited what may, politically speaking, be called a "life interest" in sanitation and State medicine generally. Schemes for the minimising of contagious disease, chiefly the so-called "malattie Celtiche" (venereal disorders); for cheapening and making accessible quinine of a superior quality in malarious districts unprovided with "farmacie"; for main drainage works and improved water-supply have, *inter alia*, been bequeathed by Baccelli among preceding Ministers, and the country should see to it, now that it is on the eve of choosing its legislators, that there is no receding from the reforms already initiated and urgently required. "Sanitas sanitatum, omnia sanitas," ought to be Italy's watchword for long years to come.

Re-opening of the Universities.

The 4th inst. witnessed the re-opening of those seats of learning in which, in the judgment of their governing bodies, the resumption of class-work would not be again interrupted by agitation, political or other, or in which guarantees were forthcoming that the regular curricula would pursue a normal and tranquil course. Catania, Messina, Naples, Palermo, Pisa, Rome, and Turin are now open, like the other royal universities of Bologna, Cagliari, Genoa, Macerata, Modena, Padua, Parma, Pavia, Sassari, and Siena. Of the free, as distinguished from the royal, universities, Ferrara, Perugia, and Urbino are also open; but Camerino remains closed. All the university institutes—those of Florence, Milan, Pisa, and Pavia—have likewise been opened. The above list is a formidable one and conveys some idea of the check given to the higher or professional education by their temporary closure due to the recent riots.

An Epidemic of Charbon.

From Sant' Angelo dei Lombardi, in the Abruzzi, is reported the outbreak of charbon on a considerable scale among the oxen and milch cows. It has now assumed an epidemic form and is steadily extending to the surrounding communes. The alarm is great, not only among the cattle dealers, but among the general public, as the authorities are found to be supine in presence of the visitation. For one thing, the period of incubation of charbon in the bovine breed is by no means ascertained, and vexatious questions have arisen, and may arise again, as to who should bear the loss incurred by the death of a cow when the animal, sold as sound, dies from charbon within a few days. Nor is the spread of the epidemic an Italian question only. There is the travelling world to be considered—not likely to be attracted when the possible sale of unsound meat or diseased milk is part of the programme!

March 6th.

Obituary.

OLIVER PEMBERTON, J.P., F.R.C.S. ENG. & EDIN.

BY the death of Mr. Oliver Pemberton, which took place on the 7th inst., Birmingham has lost one of her most noteworthy citizens and the surgical profession a sturdy link with the past. Two weeks ago Mr. Pemberton was present at the General Hospital; subsequently he took cold and was laid up with an attack of bronchitis. Apparently improving from this, he developed some symptoms of intestinal obstruction, which made his family very anxious without suspecting the real cause of the danger. These symptoms became more marked, and, in spite of the assiduous attention of Mr. Bennett May and Mr. Gilbert Barling, who sought to give him relief by opening the abdomen on Sunday morning, he gradually sank and expired the same evening. The operation revealed a condition of malignant disease which art was powerless to remove or to combat. Mr. Pemberton was born in 1825, and was consequently in his seventy-second year. His father was the principal of a well-known firm of brass founders in the town. He was educated at King Edward's School under two head masters who afterwards were raised to the episcopate—namely, Jeune, afterwards Bishop of Peterborough, and Prince Lee, afterwards Bishop of Manchester, the latter of whom declared him well fitted for a literary career. But his own wishes inclined towards medicine, and accordingly he entered as a student at the Birmingham School of Medicine, studying for four years at the General Hospital as apprentice to Mr. D. W. Crompton. He then entered at St. Bartholomew's Hospital, where his life-long friendship with Savory commenced and where he was brought into close connexion with Burrows, Stanley, and Paget. In 1847 he obtained the Membership of the Royal College of Surgeons of England, and returning to Birmingham was appointed physicians' assistant to the General Hospital, and the following year resident medical and surgical officer. In 1852 he was elected surgeon to the hospital, a post he held until 1891, when he resigned upon being elected coroner for the city. In 1878 he was elected an honorary Fellow of the Royal College of Surgeons of England, and in 1885 he obtained a seat on the council of that body. In 1886, after the death of Dr. Heslop, he was appointed one of the trustees of Mason College, and afterwards became President of the council of the college. In 1891 he was appointed by the town council to be Her Majesty's coroner for the City of Birmingham. He was consulting surgeon to several local hospitals in addition to the General Hospital, where he so long laboured and to which he was ever fondly attached. His public life was also one of constant activity and energy, and as a justice of the peace for the county of Warwick he was always to the front. As a teacher of surgery at Queen's College he commanded interest and attention from his strong common sense and aptness in imparting knowledge to others. Owing to these attributes he gained a large circle of friends, who looked upon him with more than ordinary affection. Mr. Pemberton contributed to the literature of his profession in a variety of essays, the principal ones being Clinical Illustrations of Cancer, 1867; the History, Pathology, and Treatment of Melanosis, 1858; the Ingleby Lectures on Cancer of the Female Breast, 1884; Excision of the Knee-joint; Papers on Aneurysm, &c.

During his career as surgeon he was much interested in medico-legal work, and was frequently called as an expert witness in criminal trials. One notable instance was the trial of Palmer the Rugeley murderer, when Pemberton gave evidence as to the state of the spinal cord of Cook as bearing upon the question of the poison used. Besides his medical work he took the greatest interest in the affairs of his native city. He was closely associated with the Town Library, was a member of the town council from 1879 until his election as coroner, and rendered valuable service on the health and water committees. He was an admirable coroner always sympathetic and kind to witnesses, yet never failing to draw out all important points of evidence, while his directions to the jury were always clear and judicious.

Mr. Pemberton's individuality was the marked feature of his character. He was well known by his stately demeanour, his deliberate stride, and his peculiarity of dress, a wide-brimmed hat with low crown being the prominent characteristic. His knowledge of the world, his good humour, genial expression, and kindliness of manner to all with whom he came into contact formed for him attachments of a lasting kind; while his conversational powers, general robustness of character, and his ardent love of out-door life and nature gained him many admirers. As an angler his reputation was a wide one. His methodical habits and regularity of life enabled him to get through, and be beforehand with, his daily and often arduous duties with exemplary cheerfulness. In 1851 Mr. Pemberton married the only child of Mr. Daniel Whittle Harvey, M.P. for Colchester and Chief Commissioner of Police for the City of London. He leaves a widow, three daughters, and two sons.

JAMES ARTHUR JONES, J.P., M.D., C.M. GLASG.

DR. J. A. JONES of Castle Hill, Llanelly, Carmarthenshire, died on March 1st. The deceased received his medical education at the Glasgow University, graduating M.B. and C.M. in 1876, and taking the M.D. degree in 1880. Dr. Jones went to Llanelly twenty years ago and soon became extremely popular. The deceased took a great interest in municipal matters, being a member of the local board until it was merged into the present borough council, of which he became chairman three years ago. It was through the efforts of Dr. Jones that the new town hall was erected, the opening ceremony of which was performed by his wife. He was surgeon to the South Wales, Barry, and Old Lodge Tinworks and also to several collieries. Dr. Jones had been in indifferent health for some time past, and was forty-six years of age at the time of his death. He leaves a widow and three children, for whom much sympathy is felt.

Medical News.

INTER-HOSPITAL FOOTBALL.—In the final tie of the play for the Hospitals Cup (Rugby Union rules) St. Thomas's Hospital (the holders) beat Guy's Hospital by one try to nothing. The match was played at Richmond on Tuesday last, there being a large attendance of spectators, who were rewarded by witnessing an exciting game.

UNIVERSITY OF CAMBRIDGE.—Dr. S. H. Vines, F.R.S., has been appointed a governor of the Oxford High School for Boys.—A valuable collection of plants from the Pyrenees and the Alps, mounted on about 3700 sheets, made by the late Mr. Charles Packe, has been presented by his widow to the University Herbarium.—The degree of M.B. was on March 11th conferred by proxy on Mr. W. G. Richards, B.A., of Christ's College, who is now resident in India.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The annual meeting of the Royal Hospital for Children and Women, Waterloo-bridge-road, was held in the institution on March 4th, the Lord Mayor presiding. The committee, in their report, gratefully acknowledged the liberality of several city companies, but expressed much concern at the inadequacy of the income, which had rendered it necessary to borrow £1000 from the bankers. A special Diamond Jubilee Fund had been opened in the hope of raising £10,000.

CHARING-CROSS HOSPITAL.—A meeting in aid of the special appeal for £100,000 for Charing-cross Hospital was held at the Mansion-house on March 5th. The Lord Mayor presided and the Lady Mayoress was also present. It was stated that of the sum which it is hoped to raise £50 000 will be required to discharge present liabilities and to meet the anticipated deficiency of income during the next five years, and the remaining £50,000 will be used for new buildings which are necessary for the efficiency of the hospital.

THE PROVIDENT SURGICAL APPLIANCE SOCIETY.—The annual meeting of the Provident Surgical Appliance Society was held on Feb. 25th, at the Great Eastern Hotel, Liverpool-street, the Rev. J. Greaves presiding. The report showed that the articles distributed included 3494 elastic stockings, knee-caps, and bandages, 2911 trusses and abdominal belts, 216 artificial legs and arms, and a large number of crutches, splints, spectacles, and artificial eyes. Many air-beds and water-beds had also been lent to poor patients. The income for the year amounted to £2511, and the accounts when closed showed a balance of £130 in hand.

THE ROYAL SOUTH HANTS INFIRMARY.—At the annual meeting of this institution on the 24th ult. it was reported that 1103 in-patients and 4240 out-patients had been treated last year; the receipts had been £4898, against £4631, and the expenses £5141, against £5070. There is an actual deficit of £243. Subscriptions, donations, and collections had all increased, the Hospital Sunday Fund alone being £6 less. With respect to the renovation scheme £9300 has been subscribed, including £25 from Her Majesty the Queen, and the Mayor of the county borough has expressed his willingness to place the completion of the scheme in the forefront in this year's memorials. For this £10,000 are needed. Authority was, however, given to sell out a sum of £395 to clear the balance-sheet.

LEGACIES TO MEDICAL CHARITIES, &c.—The late Mrs. Overend of Sheffield has left legacies to relatives, friends, servants, and others to the amount of £110,000, free of duty; £26,000 are left to Sheffield charities, and Church institutions receive £4000. Other institutions benefited are: Yorkshire Deaf and Dumb Institution, £2000; Birmingham Deaf and Dumb Institution, £2000; Association in Aid of Deaf and Dumb, Oxford-street, London, £1000; Children's Hospital, and Women's Hospital, Birmingham, £1000 each; St. Mary's Hospital, London, £1000; Worksop Dispensary, £1000; Cottage Hospital, Retford, £1000; Northern Counties Asylum for Idiots and Imbeciles, £1000; and National Hospital for Paralysed and Epileptic, £5000. To the following medical charities are left £1000 each: Cancer Hospital, Fulham-road, and Queen Charlotte's Lying-in Hospital; and to the Devonshire Hospital, Buxton, £500. Many other institutions have also benefited.

THE Worshipful Company of Clothworkers have sent a donation of £100 to the Royal Hospital for Diseases of the Chest, City-road, E.C.

ROYAL METEOROLOGICAL SOCIETY.—A special exhibition of Meteorological Instruments in use in 1837 and in 1897 has been arranged in commemoration of the Diamond Jubilee of Her Majesty the Queen, at the Institution of Civil Engineers, Great George-street, Westminster. The exhibition will be open from Tuesday, March 16th, to Friday, March 19th. On Wednesday, the 17th, at 7.30 P.M., an illustrated lecture will be given by Mr. G. J. Symons, F.R.S., on "Meteorological Observations in 1837 and 1897."

THE DIFFUSION OF SMALL-POX.—Since mid-February to Saturday last 10 deaths from small-pox had been registered in London, of which 6 were registered last week, 3 in vaccinated and 3 in unvaccinated persons. The 3 vaccinated individuals were all over five years of age, 2 of them being upwards of forty years of age; whilst of the 3 unvaccinated all were aged under twenty years, and 1 was a child under the age of five years. Of the 6 deaths, 3 patients belonged to Camberwell, 2 to the Strand, and 1 to St. Martin-in-the-Fields sanitary areas. Six new cases were last week admitted to the hospital ships on the Thames, as compared with 20, 3, and 18 in the preceding three weeks, and 43 cases remained under treatment last Saturday. Two cases of the disease which occurred at Devonport towards the close of last month, both in one household, were isolated in the infectious diseases hospital at Milehouse.

DIPHTHERIA IN LONDON.—Last week saw a fall in the number of deaths registered from diphtheria in London, the total of 43 being the third lowest for any week during the current year. It was, however, 9 in excess of the corrected average for the ninth week of the period 1887–96. All but one of the 43 deaths were in young persons aged under twenty years, and 25 were of children aged from one to five years. Wandsworth and Camberwell were each of them credited with 6 deaths, Greenwich with 5, and Islington with 4 deaths. The admissions to hospital in the week numbered 112, against 104, 104, and 102 in the preceding three weeks, and last Saturday found 846 patients who were suffering from diphtheria under isolation. In the outer ring there were 9 deaths registered from the disease, of which 5 were in the West Ham registration district and 3 in the Brentford district.

CARDIFF UNIVERSITY.—The Medical Students' Club of Cardiff University College entertained Professor Alfred William Hughes at dinner in the Queen's Hotel, Cardiff, on Monday evening, and presented that gentleman with a token of goodwill and esteem on his departure after having resigned the chair of anatomy. The toast of "The Health of Professor Hughes" was proposed by Dr. Donald Rose Paterson, the President of the College, who referred at length to the good influence Professor Hughes had exercised upon the success of the medical school during his four years' stay in Cardiff and emphasised the regret which all the teachers and students experienced in parting with him. Professor Hughes was then presented with a handsome spirit-stand and a silver salver, on which was inscribed a sentence conveying the regard of the students for him "as professor and friend." Professor Hughes, who had been forced to leave Cardiff on account of the health of his wife, acknowledged the compliments he had received in feeling terms.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Petroleum Lamp Accidents.

THE Select Committee of the House of Commons on this subject has appointed Mr. Mundella chairman, and has determined to take no more evidence from scientific experts as to the relative inflammability of different kinds of oil, but to push forward its inquiry as to lamps and their construction.

Proposed Conference on Insanity.

Mr. William Corbet has given the following notice of motion—viz.: To call attention to the annually increasing numbers of the insane not only in the United Kingdom, but in every civilised country of the world; and to move that it is desirable in the interests of humanity that steps shall be taken to convene an international conference to inquire

Hosted by Google

into the cause of such increase and to report whether any and what measures can be adopted to arrest the spread of the disease.

Military Head-dress.

In the House of Lords on Monday, March 8th, the Earl of Strafford questioned the War Secretary with reference to the head-dress of the Army and the various proposals for changing it, and the Marquis of Lansdowne replied that he has thought it right to refer the whole question to a committee, and that until the report of this committee is received no decision will be arrived at by the War Office.

Infant Life Protection.

A Bill is now before the House of Lords to amend the law for the better protection of infant life. It was introduced by the Earl of Denbigh.

Working Men's Dwellings Bill.

The House of Lords has given a second reading to a Bill to provide facilities for the acquisition by working men of their own dwellings. The Bill enables local authorities to make advances up to £150, and requires that they shall be satisfied that the workman actually resides or *bonâ fide* intends to reside in the dwelling-house, that the title is good, the sale made in good faith, and the price reasonable, and that the dwelling-house is in a sanitary and tenantable condition. There are a great many provisions in the Bill designed evidently to secure the local authorities against loss and to prevent abuse.

HOUSE OF COMMONS.

THURSDAY, MARCH 4TH.

Metropolitan Pauper Children.

Mr. Cohen asked the President of the Local Government Board if he would lay upon the table of the House the answers he had received from the guardians of the various metropolitan parishes to the draft order prepared by the Local Government Board for placing certain classes of children under the care of a new central authority in London.—Mr. Chaplin replied that in a large proportion of the communications he had received he was asked to defer a decision until a conference was held on the subject. This conference was held on the 26th *ultimo*, and resolutions were passed by large majorities to the effect (1) that it was desirable that separate provision such as was indicated in the draft order should be made for certain classes of children, and (2) that it should be urged upon the Local Government Board before constituting a new board to consider whether the duties created by the new order might not with advantage be conferred on some existing authority or authorities. At the conference referred to every board of guardians and the managers of each district school in the metropolis were represented by delegates, and he had received no communication from any board of guardians on the subject since the conference took place.—Mr. Lough asked Mr. Chaplin whether he would consider favourably the recommendation to reconsider the decision to constitute a new authority rather than give the work over to one of the existing authorities.—Mr. Chaplin replied that the whole matter was under consideration.

Increase of Enteric Fever in India.

Lord George Hamilton, replying to a question addressed to him by General Russell, said he had noticed with regret the increase of enteric fever in India, the causes of which were still very obscure. The Government of India had adopted various measures for improving the sanitation and water-supply of cantonments, and the question as to the means of checking this disease was one which was constantly engaging their attention.

Rabies.

Mr. Walter Long, President of the Board of Agriculture, in answer to a question on this subject put to him by Mr. Stephens, said:—The new orders which I have it in contemplation to make with regard to rabies will be issued with the least possible delay, but I would point out that those orders are intended to give effect to the recommendation of the Departmental Committee that a determined and systematic attempt should be made to stamp out rabies, not only in the metropolitan area, but throughout the United Kingdom. The adoption of this policy involves the settlement of several difficult questions, which are now engaging my active consideration, but in any event adequate notice of the new requirements must be given to the public before they can take effect. In these circumstances I have suggested for the consideration of the Middlesex County Council whether the most convenient course to be taken by them during the interim would not be that their regulations should be brought into harmony with those now in force in the other districts comprised within the metropolitan area.

MONDAY, MARCH 8TH.

Private Asylums.

Mr. Field asked the Home Secretary whether the Government would consider the advisability of the suppression of private asylums, and make other and more suitable provision for paying patients.—Sir Matthew White Ridley replied that he was not aware of any sufficient reason for disturbing the arrangement made only six years ago by Parliament with regard to licensed houses.

Suicides.

Sir Matthew White Ridley, in reply to Mr. William Corbet, said he was not aware that any useful purpose would be served by continuing the return as to the insane who committed suicide which was granted last year, and as it proved a very troublesome one to prepare he was afraid he must decline to do it. The number of insane persons generally who committed suicide would, of course, appear in the judicial statistics in the ordinary way.

TUESDAY, MARCH 9TH.

Health of Cotton Cloth Workers.

Mr. Ascroft asked the Secretary of State for the Home Department if he would consider the advisability of introducing a Bill, at as early a date as possible, with a view to carrying out the recommendations made by the committee appointed to inquire into the working of the Cotton Cloth Factories Act, 1889, &c., for the preservation of the health of the workpeople employed in the textile industries, or whether the Government would be prepared to support such a Bill if introduced by a private Member.—Sir Matthew White Ridley replied that there had not been sufficient time as yet for the full and proper consideration of the committee's recommendations, but they were being carefully considered at the present moment, and of course he should be glad to consider at the same time any suggestions which Members might desire to make.

Work in Bakehouses.

At this sitting of the House Mr. Woods introduced a Bill to restrict the hours of labour in bakehouses to forty-eight per week.

Metropolitan Pauper Children.

Mr. Pickersgill asked the President of the Local Government Board to postpone the final issue of the order with reference to the metropolitan Poor-law schools until the House had been enabled to consider the matter either on the vote for the Local Government Board or on some other occasion.—Mr. T. W. Russell, on behalf of Mr. Chaplin, declined the proposal.—Mr. Pickersgill in this connexion has given notice of a motion deprecating the formation of the proposed Metropolitan Children's Asylum Board, on the ground mainly that it will add to the confusion of authorities and to the cost of administration.

WEDNESDAY, MARCH 10TH.

Private Lunatic Asylums in Ireland.

On the motion of Mr, Field, there was ordered a return of the number of cases treated in private lunatic asylums in Ireland, the number of cures effected, and the amount of revenue derived from patients during the years 1895, 1896, and 1897.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ASHDOWNE, W. C. G., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Anæsthetist to St. Mary's Hospital, London.

BARNES, GEORGE, M.R.C.S., L.R.C.P. Ed., has been re-appointed Medical Officer of Health for the Chard Urban District.

BARROW, GEO. A., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Out-patient Department of the Children's Hospital, Manchester.

BRISCOE, WILLIAM THOMAS, M.D., M.Ch. Dubl., has been re-appointed Medical Officer of Health by the Chippenham Urban District.

BROADBENT, J. F. H., M.D. Oxon., B.Ch., M.R.C.P. Lond., M.R.C.S., has been appointed Casualty Physician to St. Mary's Hospital, London.

BROWNE, CHAS. WM., M.R.C.S. Eng., L.S.A., has been appointed Additional District Surgeon of Aliwal North, resident at James Town, vice Kitching, resigned.

CHRISTOPHERSON, J. B., M.B. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer to the Evelina Hospital for Children, London

COLLIER, H. S., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Surgeon in Charge of Out-patients to St. Mary's Hospital, London.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Mr. E. J. Reynolds: Inspection and Demonstration at Friern Barnet Sewage Works.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second volume of 1896 was given in the issue of Dec. 26th last. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

THE COST OF A COTTAGE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Being anxious to start a cottage hospital I should be very grateful if you or any of your readers would kindly give me some idea as to the cost of furnishing one of, say, seven or eight beds, also the cost of maintenance per bed per annum (instruments and splints not to be included). Apologising for troubling you,

I am, Sirs, yours faithfully,

March 2nd, 1897. ONE WHO WANTS TO KNOW.

Hosted by Google

THE DOSE OF IPECACUANHA.

To the Editors of THE LANCET.

SIRS,—One of the commonest diseases in this country is bronchitis. The disease by which more persons are killed than by any other disease is bronchitis. This is the time of the year when bronchitis is especially common, and when it kills an especial number of persons. The remedy par excellence for bronchitis is ipecacuanha. Other remedies there are, but the one in most frequent use is ipecacuanha. It may be an interesting inquiry to make at about this time whether patients affected with bronchitis are as a rule much benefited by having ipecacuanha prescribed for them. I venture to think that, as a rule, they are not much, if, indeed, at all, the better for it. Affected myself with bronchitis, and ipecacuanha wine being recommended for me, I ascertained the authoritative customary dose of this remedy from the pharmacopœias of some of the London hospitals. I find that the dose commonly administered is ten minims three times a day. Now, I have reason to suppose that in that dose ipecacuanha wine is of little, if any, use. I find that if I take half a drachm of it every two hours throughout the day it produces no apparent effect of any kind, no action of the skin, no nausea, no aperient result, no tangible expectorant effect. The wine was procured from Messrs. J. Bell and Co., and was therefore of the best quality. I have yesterday thus taken in all three drachms of ipecacuanha wine in place of the customary total of thirty minims, and this morning before noon I have taken one and a half drachms. The impression left on my mind is that I have taken far too little to produce any effect of any kind. I am therefore of opinion that the customary dose of this remedy ought to be largely increased and that such a step may be taken with perfect safety.

I am, Sirs, obediently yours,

Weymouth-street, W., Feb. 11th, 1897. BALMANNO SQUIRE.

Mr. H. G. Rogerson.—The advertisements are of the ordinary character, though perhaps more impudent than usual. We should have thought the schoolmaster might have been called to order by his employers.

Junior Practitioner.—There is no objection to such a course, provided there is no canvassing for patients.

VEGETABLE PILLS.

THE *Birmingham Mail* is responsible for the following excellent story of "the experience of a Birmingham man who purchased a box of pills from a local huckster's shop. He took some without effect. The rest were set aside in a cupboard which was very damp. After a few weeks he again sought his pills and to his astonishment each had developed a healthy green shoot, which was not rhubarb or aloes, but grew from what turned out to be a white pea covered with some white coating." We have no doubt that the Birmingham man was sore at being gulled. In our opinion he ought to be most devoutly thankful that nothing more than a harmless pea was foisted on him in exchange for his silver.

Dr. Albert Wilson of Leytonstone writes to us concerning a case of dual consciousness exhibited by him at the Clinical Society (THE LANCET, March 6th, 1897, p. 665). He writes to repudiate any connexion with the publicity given to the case and his name by a lay paper, and at the same time to invite any interested medical man to communicate with him if they should desire an interview with the patient.

"FALSE COLOURS."

To the Editors of THE LANCET.

A Disclaimer.

SIRS,—Your annotation on the *primâ facie* facts recited was intended to be just. You very fairly inferred an inconsistency between my letter and my appearance on a public platform with posters staring me in the face—M.D., &c. But this appearance is fallacious, for at the stated time and for many weeks, I was confined to a sick bed with an injured leg and neither supported the chairman (since I could not support myself) nor even knew or heard of the bills and posters which have elicited your correspondent's comment. Further (and how can I say what I wish without the appearance of arrogance or presumption?), while it may be right to show in some way that I have had a medical education, I am not desirous of appearing in any degree connected with the British medical school and Register. I say this without offence and without judging any other man's principle. But I stick to my own. I am myself convinced that the orthodox antagonistic principle of medication is a mistake, that vaccination is a blunder, and vivisection a crime. Therefore your correspondent will understand that I am sincere when I repudiate, as I have sometimes to do on the platform or elsewhere, the title of "doctor," indicating, as it is supposed to do, an orthodox, registered medical practitioner of Great Britain. These are my colours, and I am neither ashamed of them on the one hand nor flaunt them in anyone's face on the other. Another point, but one on which I shall not enlarge, is that all letters after one's name and all titles put before it should, I think, carry with them some definite idea of examinations passed and merit won, but not otherwise.

I am, Sirs, yours faithfully,

Temple, March 8th, 1897. H. S. SCHULTESS-YOUNG.

"ANTISEPTIC MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—I have, I am afraid, failed to make myself properly understood. What I meant to convey was that the experience of lying-in hospitals seems conclusively to point to the perchloride solution as the only reliable antiseptic for purifying the hands, &c., but that a strength of 1 in 2000, as quoted by Mr. Harding from an old edition of my book on midwifery, is not sufficiently strong, and that 1 in 1000 should be used. Every practical man knows that nurses will not use 1 in 50 carbolic solution effectively because of its roughening and irritating effect on the hands. The creoline solution I do not recommend as a means of disinfecting the hands—for which purpose the 1 in 1000 perchloride alone should be employed—but for addition to water used for douches or ablution after delivery. It is perfectly bland and unirritating. Sufficient creoline should be dropped into the water to be used to make it milky in appearance.

I am, Sirs, yours truly,

Grosvenor-street, W., March 5th, 1897. W. S. PLAYFAIR.

Partner.—A medical man cannot take as a partner anyone but a properly qualified person. Anyone finding capital for the purchase or conduct of a business is not a partner with the man who works the business. It is a mere matter of contract how such a capitalist should be repaid. He or she would have no control over the working of the practice, which must be left strictly to medical hands.

TREATMENT OF CORNS, &C.

A CORRESPONDENT writes:—"Can any of your readers suggest good treatment for corns and bunions? I have used salicylic preparations to corns which decrease them temporarily, but they return. As to bunions, I want a method of reducing pain, easily applicable and, if possible, to reduce size. I have had a run of patients who expect a medical practitioner to cure all minor ills."

D'Artagnan.—We have seen the article. No good would come of commenting upon it.

"LINCOLN MEDICAL PROTECTION FUND."

To the Editors of THE LANCET.

SIRS,—Will you kindly publish the accompanying statement of accounts of the above fund? Since the last published list I have received the following subscription—T. M. King, M.A., 4, Mortlake-road, Kew, £1.

I am, Sirs, yours truly,

Lincoln, March 8th, 1897. W. A. CARLINE.

Alpha.—The answer to this question clearly depends upon our correspondent's business position towards A. If he is A's employé he must do as he is told or resign his position; if he is not an employé he can act on his own responsibility.

AN INSOLENT ADVERTISEMENT.

MR. FRANK HOWARD, who describes himself as a "consulting ophthalmic optician," has issued a circular in which he offers to medical men the use of a dark room and all necessary testing apparatus for examining a patient. We have no fault to find with this offer, which might be of service to some practitioners, but Mr. Howard then goes on to say, "If you kindly send to me any patient whose errors of refraction or accommodation require correction, I should be glad to diagnose the case and submit my prescription to you for verification and approval, free of charge." This last offer is simply a piece of impertinence, and we hope that any medical man who has received Mr. Howard's circular will write telling him to mind his own business—namely, that of supplying glasses ground to a certain curvature in accordance with the formula laid down by a medical man.

SOLUTION OF CHLORINE AS A GERMICIDE.

To the Editors of THE LANCET.

SIRS,—In the early part of October of last year I thought of trying the result of the application of the old liquor chlori to some long-standing cases of varicose, indolent, and purulent ulcers, lupus, rodent and epithelial sores, and syphilis, and so happy is the result in many of these cases that I determined to investigate the matter further and had the liquor made purposely of different strengths of pure chlorine passed into sterilised water. I firmly believe we have in this liquor one of the most powerful germicides and antiseptics of the time. Towards the close of last year, through the kindness of Mr. George Stoker, I had the opportunity of seeing his interesting and successful cases under the oxygen treatment, and it confirmed my view that we wanted a more destructive germ-destroying element as well as a blood purifier and coagulator like oxygen. I have suggested the liquor to several surgical and medical friends at different hospitals as a general dressing, antiseptic and clean, immediately deodorising all foul wounds and ulcers. In cancer, syphilis, lupus, and rodent ulcer I have so far great hopes it may prove the most valuable antiseptic dressing we have; also as a spray in diphtheria, foul sore-throats, and in uterine medication. I hope soon to send a short account of cases that I have had under my observation since last October dressed with the chlorine liquor. It is especially destructive to the bacillus staphylococcus aureus, typhosus, diphtheriæ, anthracis, and coli. Probably, also, we may find it to be so with the cancer, syphilis, and leprosy bacillus; but of these I shall have more to say when my cultivations are further developed. I do not wish it to be thought that I put the view forward that "the use of liquor chlori is a new antiseptic dressing," but from all I can gather it has not been applied in this simple form, neither do I believe the valuable antiseptic germicidal character of chlorine in solution has been sufficiently estimated in surgical and medical practice.

I am, Sirs, yours truly,

Harley-street, W., Feb. 14th, 1897. JAMES STARTIN.

A. B. C.—There were two books—"Baby Buds" for very young children, and "The Human Flower" for older children. They were published by Mrs. Wolstenholme Elmy, Buxton House, Congleton. Our reviewers did not recommend these works to the favourable consideration of parents.

A. V. T. is requested to repeat the communication.

THE REVOLVER NUISANCE.

"As many as seven boys, at two London police-courts yesterday, were charged with disorderly conduct involving the use of revolvers," says the *Globe* of March 9th. "The eldest of the lot, who was said to be eighteen years, but looked younger, got a month's hard labour; the youngest, fifteen years, was let off with a fine, while the rest were remanded." Short terms of imprisonment will not stop this nuisance. Tradesmen should not be allowed to sell deadly weapons to lads in their teens, and legislation in the matter is urgently required. A bullet wound the result of an accident is far too frequent a case in the wards of our general hospitals, and although the Roentgen rays permit of the easy location of the foreign body, the scarce beds in these over-worked charities ought not to be regularly required to remedy the mischief done by a few careless young larrikins.

Douche writes: "Is there in London a well-appointed establishment where good-class patients (male and female) can be sent for cold and hot douches?"

M.D.—We shall be happy to receive the paper, but we cannot promise insertion until we have seen it.

MOTOR CARS.

To the Editors of THE LANCET.

SIRS,—Perhaps some of your readers may be interested in hearing some of my experience during the past six months with motor cars for practical work. I have been using one since the commencement of October and during all the bad weather; during this time I have found it very satisfactory. I have run one sixty miles a day for several consecutive days and in all sorts of weather and on all sorts of roads. The vibration when running is less than with a horse and trap and the speed averages ten to twelve miles on the level and five to six miles an hour up-hill. The cost of running is about ½*d.* per mile for a two-seated car. These have 1½-horse power motors on the gas-engine principle, using petrol vapour, and give off practically no smell. As such large numbers of persons are desirous of having information about them and as I am an enthusiast in regard to this new development, I have written a small book giving a short history of their development and present position, with descriptions of steam, oil, and electrical methods, and hints on management and working, illustrated. Shall be pleased to send copies of the same to any who are interested post free on receipt of six stamps.

I am, Sirs, yours faithfully,

Burleigh Villa, Harrogate, March 2nd, 1897. J. C. LUKE.

"PARKE MEMORIAL FUND."

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you would publish the subjoine list of 10*s.* subscribers to the late Surgeon-Major Parke's memorial. My letter of appeal appeared in THE LANCET of Jan. 30th.

I am, Sirs, yours truly,

Canterbury, March 3rd, 1897. PUGIN THORNTON.

Yeomanry surgeons: H. P. Symonds, G. T. Phillips, C. Stonham, C. T. Street, G. W. Welchman, E. Kingscote, H. W. Kiallmark, W. J. Naismith, and J. S. Jones.—Mrs. W. Tattersall, B. Pollard, Sir H. B. Poland, C. Hazard, G. L. Hazard, Lord Harris, Sir Wm. Jenner (second subscription), the Misses E. and L. Wardes, H. T. Butlin, R. J. Godlee, A. Critchett, General Sir P. Fielding, J. H. Mummery, C. Awdry, and A. Clark.—Surgeon-Major S. Westcott, per Messrs. Holt and Co., £1.

Dr. D. H. Attfield desires us to contradict the assertion that he has been appointed to succeed Dr. Mackie as a member of the Quarantine Board at Alexandria.

A USEFUL INNOVATION.

THE Victory Cycle Syndicate, of 42, Old Broad-street, request us to state that their Red Cross Victory cycles can be hired by members of the medical profession at £6 10*s.* per annum—an arrangement which will doubtless be welcomed by those who would prefer to hire rather than purchase a machine. As this is the only firm, so far as we are aware, making an offer of this kind, the information may be useful to some of our readers.

Fibula will find what he requires in the *American Journal of Obstetrics.*

A ROENTGEN DIAGNOSIS OF GOUT.

A RECENT communication by MM. Potain and Serbanesco at the Académie des Sciences is of interest as suggesting a new means of differential diagnosis between the deposits of gout and rheumatism. According to these observers the former show when submitted to the x rays a translucent central part limited by a narrow dark border, which again is enclosed in a wider opaque area. This central clear portion is absent in the rheumatic thickening. It is attributed to the greater permeability to the rays of urate of soda as compared with rheumatic deposits and also with the normal bone salts, a conclusion which they have confirmed by further independent observations.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Reliable Products of Scientific Pharmacy.

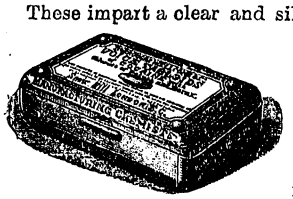
RED GUM "TABLOIDS" (B., W. & CO.).

Red Gum, an exudation from the Australian *Eucalyptus Rostrata*, is a mild styptic and antiseptic, and an excellent local and general astringent. When a Red Gum "Tabloid" is allowed to dissolve in the mouth the continuous action of the drug on the mucous surfaces of the throat is fully secured. Great care has been exercised so to adjust the relative proportions of the ingredients that the full therapeutic effect of the drug may be obtained without offending the palate or affecting the appetite.

Supplied in metal boxes of 30 or bottles of 100 "tabloids," at 5d. and 1s. each.

CHLORIDE OF AMMONIUM "TABLOIDS."

The solvent and discutient powers of Chloride of Ammonium have led to its extensive employment in throat and bronchial affections attended with abundant secretion of thick and tough phlegm. It immediately mitigates cough from pharyngeal or bronchial irritation, and facilitates expectoration. In cases of weakness or lack of tone of the vocal organs from straining and over-exertion, Chloride of Ammonium "Tabloids" slowly dissolved at the back of the tongue act as a rapid restorative. Two or three "tabloids" will sometimes entirely relieve pharyngeal cough and throat affections in which other remedies have not been effectual. Ammonium Chloride "Tabloids," 3 grains, in bottles of 30 and 100, at 5d. and 8d. each; 5 grains, in bottles of 100, 10d. each; 10 grains, in bottles of 100, 1s. 6d. each.



TAR "TABLOIDS."

In the *Medical Press and Circular*, November 20, 1892, a distinguished physician gives a further contribution on the "Mode of Administering Tar," and, in conclusion, says: "I have recently had my attention called to 'Tabloids' of Tar, containing 1 grain in each, and these, I think, constitute *by far the best mode of administering the drug*. They contain the whole of the constituents of Tar, and they are palatable and speedily disintegrate. The usual mode of administration is three or four every four hours; but a better plan is to suck one frequently, in fact every time the cough is troublesome."

Tar "Tabloids" are supplied in bottles of 50 and 100, at 5d. and 9d. each.

VOICE "TABLOIDS."

These impart a clear and silvery tone to the voice. They are easily retained in the mouth whilst singing or speaking, and are used by the leading singers and public speakers throughout the world. Supplied in metal boxes at 8d. and 1s 3d. each, and in vinaigrette ovals at 8d. each.

EMOL-KELEET.

Since our earlier notices to the medical profession regarding this preparation we have received many encouraging reports of the beneficial effects of its use in Surgery and Dermatology. It has not only been prescribed as an absorbent, anti-pruritic, and emollient, but also as a diluent for such antiseptic agents as Loretin, Dermatol, Iodoform, Boric Acid, Chrysophanic Acid, Hydro-Naphthol, &c.

Owing to the fact that it is a natural powder containing a large proportion of native silicates, "Emol-Keleet" is chemically stable, and is therefore freely prescribed as a diluent for potent medicinal agents without fear of combination taking place. In addition to these chemical advantages, its soft silky texture, soothing influence, and other physical qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other drying and dusting powders have failed.

THE LANCET, in an appreciative notice of this preparation, says: "On account of its remarkable velvety smoothness it should possess a unique value as a dusting powder in the treatment of cutaneous diseases, &c., and for allaying irritation. We have not examined a more unctuous earth."

Price 9d. per box.

SAXIN "TABLOIDS."

Saxin has been aptly termed "the sweetest thing on earth," being about 600 times sweeter than sugar and double the sweetness of saccharin. It is perfectly harmless, as it undergoes no change in its passage through the digestive system, but simply imparts its delicate sweet flavour to the food or fluid with which it is used. For these reasons it is indicated in such conditions of disease as diabetes mellitus, gout, obesity, glycosuria, etc., in which the patient is debarred from taking sugar, and yet retains an intense desire for the sweet flavour to which the palate has by long use become accustomed.

Saxin has important qualities which render it superior to other sweetening substances. It is unfermentable and permanent. It acts antiseptically, and prevents decomposition. In flavour it is more delicate than any other sweetening agent, and, in the shape of Saxin "Tabloids," ¼ gr. each, it provides the maximum amount of sweetening power in the smallest possible space. A small bottle, containing 100 or 200 "tabloids," can be carried in the vest pocket without the slightest inconvenience, and thus the patient who must avoid sugar can have a delicately flavoured, harmless sweetening agent always handy when at business or when travelling at home or abroad. Saxin "Tabloids," ¼ gr., are each equivalent to one lump of best loaf sugar, and are supplied in bottles of 100 and 200 "tabloids," at 7d. and 1s. 1d. per bottle.

NEW MEDICINES.

BISMUTH SULPHOCARBOLATE.

An excellent Intestinal Disinfectant. Successful in the treatment of Fermentative Dyspepsia. Strongly recommended for use in Typhoid Fever, Gastritis, and various Gastric Derangements. A good dusting powder in Eczema, Wounds, Sores, &c., possessing very drying properties.

Dose 5 to 20 grains. Price 8s. 6d. per lb., 8d. per oz.; or in Flexible Capsules, 1s. 6d. per box.

BISMUTH OXYBROMIDE.

The best preparation of Bismuth for making a satisfactory emulsion. Gives excellent results in Nervous Dyspepsia, Hysterical Vomiting, Gastric Irritability, &c. Recommended in cases of Indigestion from excessive brain work, nervous exhaustion, &c.

Dose 5 to 20 grains. Price 8s. 6d. per lb., 8d. per oz.; or in Flexible Capsules, 1s. 6d. per box.

LIQ. CALCIS IODINATÆ.

A Solution of Hypoiodite of Lime. The best preparation for administering Iodine in an active form. Has been used very successfully in Diphtheria, Scarlet Fever, and various septic conditions. Iodine is set free in the stomach; hence, LIQ. CALCIS IODINATÆ has the usefulness of free Iodine without its drawbacks.

ANIMAL EXTRACTS.

ARTICULAR EXTRACT.
Prepared from the fresh Articular Cartilages and Synovial Membranes of healthy animals. In Bottles, 3s., 5s. 6d., and 10s.

SUPRARENAL PREPARATIONS.
1 oz. Bottles of Tincture of Suprarenal Glands, 2s. 6d.
Pills, in Bottles, 2s. 9d. and 5s.
Tablets, in Bottles, 3s. 6d. and 6s. 6d.

BONE MARROW EXTRACT.
Dose: Half to one teaspoonful two or three times a day.
In Bottles, 3s., 5s. 6d., and 10s.

THYROID EXTRACT.
(For MYXŒDEMA). Price, in Bottles, 3s.

EXTRACTUM CORTICIS CEREBRI (Brain Extract).
Price, in Bottles, 3s. and 5s.

PITUITARY BODY PREPARATIONS.
Fluid Extract, 2s. 6d. per oz. Bottles.
Elixir, Bottles, 3s., 5s. 6d., and 9s. each.
Tablets, 3s. 6d. and 6s. 6d. per bottle.

THYROIDINE
Containing the active principle of the Thyroid Glands of the sheep, 4 grains equal to about one-eighth of a fresh gland. Also PILLS and TABLETS, each containing a dose of Thyroidine. In Bottles, 2s. 6d. each.

The Milroy Lectures

ON

QUARANTINE.

Delivered at the Royal College of Physicians of London on March 11th, 16th, and 18th, 1897,

BY WILLIAM COLLINGRIDGE, M.A., LL.M., M.D., D.P.H. CANTAB.,

MEDICAL OFFICER OF HEALTH OF THE PORT OF LONDON.

LECTURE II.[1]

Delivered on March 16th.

MR. PRESIDENT AND GENTLEMEN,—In my first lecture the important report of the Social Science Quarantine Committee in 1861 was referred to and a summary of its conclusions quoted. The evidence that was then collected was not allowed to remain long unutilised. In 1868 a powerful deputation of the medical profession presented a memorial to the Privy Council in which they urged that the subject of quarantine had for the last twenty years been under the notice of the public, and that the present system had utterly failed during its trial in 1831–32, and had moreover been productive of serious inconvenience and distress, especially to the lower classes; that the General Board of Health had already recommended the substitution of sanitary precautions for quarantine; that the International Conference of 1851 had proved abortive in consequence of the serious difference of opinion among its members; that the experiment of superseding quarantine had already been tried in 1852, when mail steamers arriving which had had yellow fever on board during the voyage were admitted to pratique after removal of sick and disinfection of vessel; that again during the Crimean War quarantine had been almost everywhere superseded; that when in 1857 an outbreak of malignant fever occurred at Bengazi on the north coast of Africa, and freedom of intercourse was interrupted for two months by quarantine, the disease did not spread in that place and rapidly ceased upon the adoption of sanitary measures; that cholera in 1865 produced such an impression that the Conference of 1866 was initiated, and after a lengthy sitting resulted in a report condemning lengthy quarantine and recommending the substitution of a system of lazarets and health police at all ports; that at no period had the restrictive measures against cholera been so rigorously carried out as during the last two years and a half, and these having been recently applied to mail steamers it was desirable that the public should be informed as to the reason for such adoption; that quarantine had been stated in Parliament to be resorted to by this country not on medical or public health grounds, but solely for commercial purposes to meet the requirements of foreign Powers; that much of the uncertainty and obscurity surrounding the subject arose from want of evidence, no committee having considered the question since 1824; and that, inasmuch as no country was or could be so deeply interested as England on account of the magnitude of her commercial relations with all parts of the world, and as undoubtedly a well considered expression of opinion from this country after a searching investigation could not fail to have great weight with other States, and would eventually lead to the universal adoption of a more rational system, they urged that a thorough and exhaustive inquiry should be made by means of a Royal Commission.

The next International Conference, held in Constantinople in 1866, came to the conclusion that cholera always had its origin in India, and its extension simply followed the lines of human intercourse, being carried chiefly by means of the infected evacuations, and spread freely only in places where the sanitary condition was bad, but that it might also be conveyed by means of clothes, vessels, and houses. They were of opinion that a rational maritime quarantine was capable of arresting the disease. Such quarantine should be either quarantine of observation or quarantine of rigour.[2] Strict quarantine was to be applied to (1) all ships from an infected port with a foul bill of health; and (2) any vessel which had had cases on board during the voyage, although provided with a clean bill. The term of strict quarantine for persons was fixed at ten days to commence from the time of entering the lazaret, to recommence if any case occurred thereafter. It was further decided that any person suffering from diarrhœa should be detained at the end of the full period until the non-choleraic nature of the disease was proved by the medical officer. It was, however, agreed that in the case of vessels carrying surgeons and complying with certain formalities, which had had no cholera or choleraic diarrhœa on the voyage, the time spent on such voyage might be taken into account, and that twenty-four hours' surveillance might be deemed sufficient. Thus, if the voyage had occupied twenty-four hours nine days of observation were necessary, but if the voyage extended to nine days only twenty-four hours of observation were required. Merchant vessels not carrying surgeons, if they had been at sea fifteen days without any cases, were to be allowed pratique after five days of observation. In the case of emigrant ships with cholera on board the limit of quarantine might be extended to any time that the local authority deemed necessary.

In 1873, so far as cholera was concerned, quarantine was officially abandoned in this country, and medical inspection substituted by an Order of the Local Government Board. This Order required that every vessel found by Her Majesty's Customs to be infected[3] with or suspected of cholera on arrival should be detained and reported to the medical officer of health of the port. Such medical officer on visiting the vessel, if he found the vessel to be so infected, had authority to order her to moor or anchor at a specified spot. Every person on board was to be medically inspected; those found healthy were to be allowed to land, and the sick removed to hospital, or if too ill detained under treatment on board. The master, under the directions of the medical officer of health, was to disinfect the vessel and to disinfect or destroy as directed any articles of clothing. The penalty for refusing to obey or carry out any of the regulations rendered the offender liable to a penalty of £50.

In 1874 another International Conference was held at Vienna, the object being "to arrange among the Powers interested compulsory regulations having as their object to bring about a perfect uniformity in the measures to be adopted against the common danger," and also to consider as to the advisability of establishing a permanent or temporary International Sanitary Commission. Twenty European States were represented, also Persia and Egypt. This Conference re-affirmed the decisions arrived at in Constantinople that cholera originated in India, that it was transmissible by human agency, and that it might be conveyed from an infected place by means of clothing which had been worn, and especially by such as had belonged to persons suffering from cholera. They unanimously decided that the disease could be conveyed by fluids, especially by water. There was a want of unanimity on the question of danger of infection from merchandise. The incubation period of cholera was fixed at a few days—a week at the outside. As to quarantine a resolution of a committee (appointed to consider the question) to the effect that when cholera had broken through the chief points of interruption quarantines in the ports of continental Europe were useless, inasmuch as land communications deprived them of all their value, was carried by a majority of twelve to eight only. In the majority were Great Britain, Germany, Russia, Austria-Hungary, and Italy, France being the only Power of the first rank among the minority. The next resolution of the committee—"Under these circumstances it is necessary to establish in the ports of Europe, instead of quarantine, a rigorous sanitary inspection of every vessel coming from an infected port in accordance with the following regulation," was also adopted. This

[1] Lecture I. appeared in THE LANCET of March 13th, 1897.

[2] Quarantine of observation was to consist of keeping isolated and under observation for an indefinite period to be fixed by the local authority a vessel with crew and passengers, with free ventilation but no disinfection. Strict quarantine was defined as the isolation for a fixed time of a ship and persons on board, with disinfection of all that might contain the germs of the disease. The whole of the cargo was to be landed, and the passengers disembarked at a lazaret.

[3] A vessel shall be deemed to be infected with cholera in which there is or has been during the voyage or during the stay of such ship in a foreign port in the course of such voyage any case of cholera.

Hosted by Google

regulation was to the effect that local sanitary authorities at every port were to be kept informed respecting cholera in other ports. Immediate free pratique was to be given to all vessels from non-infected ports which had had no communication with any infected ship or port and which had had no case of cholera on board. It also provided for the medical inspection of all vessels from infected or suspected ports and also of vessels which, though coming from non-infected ports, had communicated with infected ports or ships during the voyage or which had cases on board. Immediate pratique was to be given if there were no actual cholera on board, unless there had been cases, in which event the ship itself, the crew, passengers, their clothes and goods, were to undergo disinfection before pratique was granted. If any cases were found on board, they were to be removed to hospital, the crew and passengers (healthy) disinfected and also the vessel itself. Free pratique was to be given to all merchandise except rags and susceptible objects. As, however, some of the States (eight having voted against the abolition of quarantine) would not accept medical inspection, and as there was a possibility of improving the system without actually abolishing it, a *règlement quarantenaire* was adopted for the benefit of such Powers. Vessels arriving from infected ports were to submit to observation for a period varying from one to seven days, and in exceptional cases this might be extended to ten days. If the voyage had lasted seven days without any case on board, the detention was to be for twenty-four hours only, in other cases from three to seven days, according to circumstances, dating from time of medical inspection. In such cases, if the vessel were in good sanitary condition, the quarantine could be performed on board and the unloading of the ship was not compulsory. If there were or had been any cholera or suspected cholera on board, the term of quarantine for healthy persons was to last the full seven days, to date from time of admission into the lazaret, the sick to be landed and isolated from the healthy. The ship and all susceptible objects were to be submitted to rigorous disinfection, after which those persons who had remained on board were to undergo seven days' observation. For vessels arriving from suspected ports (which were defined as those adjacent to or having free intercourse with infected ports) the duration of quarantine was not to exceed five days. Vessels carrying emigrants or pilgrims were to be dealt with by special rules to be made by each port authority according to its own discretion. Thus for the first time was medical inspection formally adopted in the place of quarantine by a majority of European Powers, and in the case of those who still clung to the old system some important modifications were adopted. While, however, so large a minority refused to accept the decision of the majority it was obvious that but little could be accomplished.

In 1883 regulations were again issued by the Local Government Board for dealing with cholera, and these contained several new and important modifications from the Order of 1873. The duty in the first place of deciding as to the state of health of the vessel on arrival devolved, as heretofore, upon the officers of H.M. Customs, and the subsequent treatment of any vessel found to be infected upon the port sanitary authority. Independent authority was, however, given to the medical officer of health to visit and examine any vessel from an infected port whether she had previously been visited by the Customs or not, and a form of certificate was given by the medical officer to use in any case in which he had reason to believe a vessel was infected within the meaning of the Order. On the delivery of this certificate the vessel was entirely under the control of the medical officer of health.

In 1890 regulations were again issued and power given to the medical officer of health to require in the case of an infected vessel (defined in the Order as a vessel in which there is or has been during the voyage or during the stay of such ship in a port in the course of such voyage any case of cholera) the names and addresses of all passengers on board who were found on medical inspection to be healthy, before they were allowed to leave. By forwarding such names and addresses to the sanitary authority of the district to which they were about to proceed, it was placed in the power of each district by timely notice of such arrival to protect itself by keeping such persons under observation so long as deemed advisable.

In 1893 was held at Dresden the last International Sanitary Congress, at which were represented Germany, Austria-Hungary, Belgium, Denmark, Spain, France, Great Britain, Greece, Italy, Luxemburg, Montenegro, the Netherlands, Portugal, Roumania, Russia, Servia, Sweden and Norway, Switzerland, and Turkey. England was professionally represented by Dr. Thorne Thorne, the medical officer of the Local Government Board, to whose able advocacy of medical inspection as a substitute for quarantine the Conference in a great measure owes its successful results. Three committees were appointed, the first to deal with the duties of a Government when cholera appeared in a country, the second to deal with the measures necessary to prevent cholera entering a country or spreading from one part of a country to another, while the third devoted itself to the Danube traffic. The Convention was finally signed by the delegates of Germany, Austria-Hungary, Belgium, France, Great Britain, Russia, Switzerland, Luxemburg, Montenegro, and the Netherlands. This Convention was of such an important nature, and will of necessity exercise so powerful an influence upon all sanitary regulations of this country, that its chief provisions must be quoted. The Convention will last for five years from the date of ratification. It will be renewed every five years by tacit consent unless renounced by one of the high contracting parties six months before the expiration of this term. Such renunciation will affect only those countries which shall have notified. The Convention will remain in force for the other States. The high contracting parties also reserve the right to make, by means of diplomatic negotiations, such modifications as they may judge necessary to introduce into the Convention.

MEASURES INTENDED TO KEEP ALL THE GOVERNMENTS WHO HAVE SIGNED INFORMED AS TO THE PROGRESS OF AN EPIDEMIC OF CHOLERA; AND ALSO THE MEANS EMPLOYED TO PREVENT ITS PROPAGATION AND IMPORTATION INTO HEALTHY PLACES.

The Government of the infected country is to notify to other Governments the existence of a cholera centre (*foyer*). This measure is essential. This will have no real value unless the notifying Government is itself warned of actual and suspected cases of cholera occurring within its territory. It will not, therefore, be necessary to recommend to the various Governments the compulsory notification of cholera by medical men. The object of the notification will be the starting point of a cholera centre, the date of outbreak, the place where it has appeared, the number of cases reported, and the number of deaths. Isolated cases will not necessarily be notified. The notification will be made to the diplomatic or consular agencies in the capital of the infected country. For those countries which are not represented there the notification will be made by telegraph to their Governments. This first notification will be followed by later communications at regular intervals of not less than a week, so as to keep the Governments informed as to the progress of the epidemic. Information as to the appearance and progress of the epidemic will be as complete as possible, especially indicating the steps taken to prevent the spread. It will point out the prophylactic measures (1) for sanitary inspection or medical inspection; (2) for isolation; and (3) for disinfection and precautions taken with regard to ships and the exportation of goods liable to carry infection. It is understood that neighbouring countries reserve the right to make special arrangements for organising a system of direct communication between the administrative officers on their frontiers. The Government of each State shall at once publish the measures it finds necessary to prescribe with reference to goods coming from an infected country or district, and also the cessation of such.

Conditions under which a district is to be considered "infected."—Every district is to be considered as infected when an outbreak of cholera has been officially declared. It will cease to be considered as infected if there has been no death and no fresh case for five days, provided that the necessary system of disinfection shall have been carried out from the commencement of the outbreak. Isolated cases will not render a district infected.

Necessity for limiting to infected districts the measures intended to prevent the spread of the epidemic.—The Governments should apply restrictive measures only to goods coming from infected districts. But this limitation should only be accepted on the distinct understanding that the Government of the infected country takes steps to prevent the exportation of dangerous goods coming from the infected district. When a district is infected no restrictive measures shall be taken with respect to goods which shall have left it at least five days before the outbreak of the epidemic.

MERCHANDISE, OR ARTICLES LIKELY TO CONVEY INFECTION, CONSIDERED FROM THE POINTS OF VIEW OF PROHIBITION OF TRANSIT AND DISINFECTION.

Importation and transit.—The only articles which can be prohibited are:—1. Body linen, clothes, and garments that have been worn (effects in use); beds which have been used. When these articles are carried as luggage or by reason of change of domicile they come under special regulations. 2. Rags and worn-out clothes. The following ought not to be prohibited: (*a*) rags compressed by hydraulic pressure, which are carried as merchandise in bulk in bales hooped with iron, and bearing marks and numbers of origin accepted by the authority of the country of destination; and (*b*) new pieces coming direct from cotton, woollen, clothing, or bleaching factories, artificial wools (Kunstwolle, shoddy), and cuttings of new paper. The transit of merchandise or susceptible articles packed in such a way that they cannot be handled *en route* should not be forbidden. When goods or susceptible articles are transported in such a way that while in transit they cannot come in contact with soiled articles their passage through an infected district should not be an obstacle to their entry into the country of destination. No goods will be prohibited from entry if it be proved that they were sent off five days before the outbreak. Goods must not be detained in quarantine on the frontier. Prohibition pure and simple or disinfection are the only measures that can be taken.

Disinfection.—Baggage: Disinfection will be compulsory for dirty linen, clothes, and garments which form part of baggage or furniture coming from a district declared infected. Merchandise: Disinfection will only be carried out for goods and articles which the local sanitary authority shall consider as infected or those the importation of which can be forbidden. The authority of the country of destination shall fix the method and place of disinfection. Disinfection shall be carried out so as to cause as little damage as possible. Letters and correspondence, printed matter, books, journals, and business documents (except parcel-post packages) will not be disinfected or restricted in any way.

MARITIME MEASURES.—PORTS.

A vessel which has cholera on board or has had a fresh case within seven days is to be considered as infected. A vessel which has had cholera on board on leaving or during the voyage, but no fresh case within seven days, will be considered suspected. A vessel coming from an infected port which has had no death or case of cholera on board before arrival, during the voyage, or on arrival, will be considered healthy.

Infected ships are treated as follows: (1) The sick are at once removed and isolated; (2) other persons are to be also landed, if possible, and submitted to observation, the duration of which shall vary according to the sanitary condition of the ship and length of the voyage, but will in no case exceed five days; and (3) dirty linen, effects in use, and articles belonging to the crew and passengers which in the opinion of the local sanitary authority are considered infected will be disinfected, as also the vessel or only that part infected.

Suspected ships are submitted to the following treatment: (1) Medical inspection; (2) disinfection—soiled linen, clothing in use, and articles belonging to the crew and passengers which in the opinion of the local sanitary authority are infected will be disinfected; and (3) bilge water will be pumped out after disinfection and good drinking-water substituted for that stored on board. It is advised to submit the crew and passengers to surveillance from a health point of view for five days from the date of arrival. It is also advised that the cargo be discharged quickly.

Healthy ships will be admitted to free pratique whatever the nature of their bill of health. The only measures which the local sanitary authority can apply to them are those applicable to suspected ships—viz., medical inspection, disinfection, emptying bilges, and substitution of water. It is advised to keep the crew and passengers under supervision for a period of five days, reckoned from the date of leaving an infected port. It is understood that the competent authority of the port of arrival can always demand a certificate stating that there has been no case of cholera on board the ship at the port of departure. The competent authority of the port will take into consideration in carrying out these measures the presence of a surgeon and disinfecting apparatus on board vessels of the three above named classes. Special measures may be taken in the case of crowded ships, especially ships carrying emigrants or any vessels in a bad sanitary condition. Goods coming by sea can only be treated as regards disinfection and prohibition in the same way as goods carried by land.

Any vessel which is unwilling to submit to the obligations imposed by the authority of the port will be at liberty to put out to sea. She will be allowed to discharge her cargo after the necessary precautions have been taken: (1) Isolation of the ship, crew, and passengers; (2) emptying of bilge water after disinfection; and (3) substitution of good drinking water for that stored on board. She will also be allowed to disembark those passengers who desire to go on shore, on condition that they submit to the measures prescribed by the local authority.

Every country shall provide at least one port on the shore of each of its seas with arrangements sufficient to receive a ship whatever its health condition may be. Coasting vessels will be the object of a special regulation to be established between the countries interested.

Although the agreement arrived at does not establish a perfect system, it marks a prodigious advance, and it must not be forgotten that there were great difficulties to be overcome and many prejudices to combat, which could only be met by concession whenever possible without sacrificing the broad general principles involved. The keeping under observation of healthy persons arriving in healthy ships was thus agreed to by Great Britain on the distinct understanding that this in her case would not involve any actual detention, but would be covered by the forwarding of the name and address to the sanitary authorities of the district to which they were about to proceed. Shortly after this Protocol had been signed a Bill was prepared to abolish quarantine in this country, but owing to the change of Government and various other difficulties it was not until September, 1896, that the Public Health Act became law.

By this Act the powers of the Privy Council to deal with cholera, yellow fever, and plague were transferred to the Local Government Board, who were thereby empowered to make regulations for the various sanitary authorities concerned. These regulations now in force practically extend the cholera regulations, with certain modifications, to these three diseases. If a vessel is found to be infected by the officer of Customs, she is reported to the medical officer of health, who detains her and deals with her at his discretion. He has, moreover, the power of boarding any vessel for the purpose of ascertaining whether she is so infected without the previous intervention of the Customs authorities.

Thus for Great Britain quarantine has been formally abolished, and our protection henceforth against the importation of infectious disease will be medical inspection, without any vexatious detention of a healthy vessel merely because she has arrived from an infected port. This, shortly, has been the history of quarantine in this country, and it now remains for time and experience to demonstrate to other countries the value of our system in order to induce them to accept the same conclusions. With many this will be readily brought about, while others will have more difficulty in arriving at the same opinions.

Having thus sketched the history of quarantine in this country and its final supersession by medical inspection it is necessary to inquire somewhat into the causes which have gradually led to its abandonment. The chief of these are: (1) That the system of quarantine was based upon a theory which is no longer tenable; (2) that when carried out as strictly as possible it has not had the effect of arresting the importation of disease; (3) that it has never been found possible to maintain quarantine absolutely, and that consequently a country practising it has been subjected to a barbarous, unnecessary, and costly system, without even the satisfaction of knowing that the experiment was complete; and (4) that sanitation and a rational system of medical inspection have proved more efficacious and at the same time less burdensome.

1. That the system of quarantine was based upon an untenable theory. In the early days of quarantine the idea of contagion was scarcely considered, inasmuch as diseases were looked upon as of Divine origin and represented the punishment by a higher authority for some special sin. The whole theory of modern quarantine, however, rests upon an assumption that certain diseases are conveyed by contact and by contact alone. Obviously if this assumption were capable of proof there would be a strong theoretical case for its adoption, though the practical test would still have to be rigidly

Hosted by Google

applied. In the fifteenth century the idea of contagion was attracting much attention, and as the transmissibility of disease from one individual to another became more and more clearly proved it was not unnaturally assumed that this was the only manner in which such transmission could be effected. Medical science was then, however at a low standard, and the methods of inquiry into the nature and causes of disease were unscientific and uncertain. It undoubtedly was a great stride to have passed from the supernatural idea of epidemic diseases and to recognise in any degree the influence of human agency. Inasmuch as plague was the only disease against which quarantine was at first instituted (and was for a long time so limited) on account of its supposed spread by contact alone, as other diseases came to be considered as contagious the system was as a matter of course extended to them. There is a certain amount of reason in the principle underlying the whole question—viz., that persons suffering from certain diseases may under certain specified conditions be the means of communicating the disease to other individuals, but here the rationale stops. The medical profession[4] at that time taught that the method of propagation of disease was not only by inhalation of the breath or effluvia from a sick person, but by absorption of the virus into the system through the skin, consequent upon direct contact. Hence it was that we read of physicians having recourse to complete oilskin dresses during epidemics, with the object of protecting themselves from coming in contact with infected persons, and it was "on this hypothetical extravagance that quarantine legislation was based, to the no small discredit of medical science, the misleading of governments, and serious damage to private and public interests."

One of the striking characters of the plague has been its sudden origin and development in various places in the East quite independently of any apparent connexion with its previous appearance in the same or other localities. So firmly, however, was the theory of contagion implanted in men's minds that the most extravagant and fanciful causes for the origin of an outbreak were accepted rather than any admission should be made as to the possibility of its arising in any other way. Thus, Dr. Bowring mentions a case in Egypt where, a contagionist having shut himself up in his house for protection and having died from plague, the explanation given was that his son had flown a kite from his window and that the kite had come in contact with a bird flying from an infected part of the city. In another case the entrance of disease into a strictly quarantined house was stated to have been due to a cat which had been seen on a basket of clothes returning from the laundry, these clothes having probably belonged to some person who had had plague; while M. Lamont, a writer on plague at the beginning of the century, attributed its introduction into Leghorn to a mummy which after twenty centuries of interment was unrolled in that city. Thus, again, in Malta, in 1813,[5] the outbreak was very generally attributed to the theft by a smuggler of a bale of cotton from a vessel which had arrived from Alexandria, although there had been no sickness on board; while that of Corfu twenty years later was supposed to be traceable to contagion remaining latent in a hat belonging to an officer who had died at Malta, the hat having been sent to his friends at Corfu. It was assumed that because a disease is at times transmissible from one individual to another, therefore the property of contagion is an absolute and essential attribute. It is well known that the activity of contagion varies greatly, as is well seen in epidemic seasons by contrasting the different degrees of activity during the various stages of its existence. Thus, during the height of an outbreak the activity of contagion is far greater than during its decline, a fact which harmonises with our present knowledge of the theory of infective disease. Perhaps one of the strongest proofs of the belief in the theory of contagion exists in the practice of quarantine officers who invariably put their questions when inspecting ships from a boat alongside and never go on board the vessels themselves until they have been admitted to pratique. As to the different amount of risk between going alongside and actually going on board the evidence of Dr. Dickson, the medical officer of Her Majesty's Customs, is of great interest: "As these officers spend their lives on board vessels from abroad, all of which are for a longer or shorter time under their surveillance, their sanitary condition may be considered a fair criterion of that in the port in connexion with its foreign trade. Their almost entire exemption from zymotic diseases not only in this but in preceding years is very remarkable. Even in the great cholera visitation of 1866, when they were of necessity often living on ships from infected countries, no instance of the malady occurred among them. Dr. Russell of Gravesend, who has been in immediate charge of a section of this force for nearly half a century, has hardly known an instance of a Custom-house officer being infected from contagion on vessels where they have been boarded, and from my knowledge of the numerous London division, whose daily business is on ships in dock discharging cargo, I can fully corroborate his statements."

But plague was held to be conveyed not only by the direct contact of individuals, but also by other persons who have been in contact with them and the various articles of merchandise carried as cargoes. Hence arose the distinction in all quarantine regulations between "susceptible" goods—i.e., those that were capable of carrying the poison—and "non-susceptible"—those incapable of so carrying it. It is somewhat difficult to understand how this arbitrary distinction arose. It is sufficient to quote one or two instances to show how fanciful and absurd the distinction was. Thus in 1840 in Italy bars of iron were passed through the fire in order to destroy infection. In 1846 tallow and wax were classed as "non-susceptible," while candles were placed on the "susceptible" list. Old copper and metal were "susceptible," while wood was "non-susceptible." The plague of London in 1665 was stated by Hodges to have been imported by means of bales of cotton. But careful investigation showed that the registers furnished evidence of death from this disease for some years previously to the general outbreak, while the disease had existed in Europe for centuries. When epidemic plague raged in Alexandria and all the servants and employés of the Egyptian Government were daily handling bales of cotton which were afterwards exported, although no precautionary measures were taken, there would seem to have been no infection carried by such goods. At the lazarets of Marseilles it is stated that not one of the porters discharging cargoes from suspected vessels has ever been attacked. Sir Wm. Pym, the Superintendent of Quarantine, says: "I could not ascertain that any one case of plague had been introduced in any of the lazarets I visited in consequence of the importation of merchandise"; and, again: "From what I have stated as to the non-appearance of plague in any one instance from the manipulation of merchandise in the lazarets the present practice of exposing goods to the atmosphere for a certain period appears to have been attended with success." Dr. Milroy, in commenting upon this, wisely remarks that probably it had never occurred to him that they need not have been contagious at all, and that the process of airing was possibly an unnecessary farce. Dr. Patrick Russell, in his treatise on the plague in 1791, says: "One custom of the merchants is on very hot days to take their walks in lines and in the shades made by packs of flax, that is an infamous plague keeper, and is brought from Cairo, famed for being the fountain and granary of plagues, where they were supposed to be bred and from thence propagated to all other countries. Nay, a head of flax is hung out of every pack for a sample of the whole, which those merchants make no doubt to examine every bargain they make. So little do they know of a plague of pestilence being conveyed by these goods that they handle and examine them rapidly, even flax of the growth of Grand Cairo."

In his communications as to the mode of diffusion of the plague in the epidemic of Hillah and Bagdad in 1876–1877 Cabiadis[6] gives as his conclusions that mere contact with an infected person is without danger if not unduly prolonged, and that persons living in the same house, however carefully they may isolate themselves, are usually attacked. Again, recently, during the outbreak of plague in Hong-Kong, it has been shown by Dr. Lowson that the disease is not contagious, nor is it conveyed by the breath of a sick person. He quotes as proof the fact that none of the party told off to visit or remove those affected with plague were attacked, although they spent four hours daily in the most infected houses in the city, while none of the attendants on the *Hygeia* hospital ship suffered from the disease, although the patients were not only overcrowded, but on account of the difficulty of obtaining washermen were allowed to remain in a filthy state

in their dirty clothes. At the Chinese hospital the state of things was even worse; but although the building was over full with dead and dying, the atmosphere being "indescribably bad," none of the attendants contracted the disease, though they often slept in the wards with their patients. Dr. Lowson concludes that the infection is conveyed much in the same way as phthisis is, by the sputum of the patient.[7] Staff Surgeon Wilm, R.N., invariably found the plague bacillus present in the fæces of the sufferers.

Yellow fever is no longer considered as a contagious disease, but it is undoubtedly transmissible by means of an infected ship. Professor Bailey of Louisville,[8] in 1879, speaks of the transmission of a section of the climate of a yellow-fever district, and states that the ships brought something from the climate and not from the sick. "For this something to be effective it was requisite that the locality into which it was imported should have for the time being a temperature equal to and approximate to that of a true yellow-fever district, and from this point of view a quarantine including persons was an elaborate folly." Yellow fever, perhaps, presents a stronger case against quarantine than any other disease. In addition to its uselessness, which will be dealt with later on, it is in this disease that the greatest danger arises from its exaction. The fact that the vessel itself is infected is an argument for treating her as rapidly as possible for the destruction of the infection, but certainly not for retaining healthy persons on board exposed to the danger, which is increased by the fact that, instead of being at sea and exposed to free air and ventilation, she is lying still in port or harbour. The longer such a vessel is detained in quarantine the greater the actual danger, assuming infection to exist. Dr. Vanderpoel[9] says: "The longer such a vessel is allowed to remain untouched—i.e., the longer a quarantine is enacted—the greater will be the virulence of the disease and the greater the danger of spreading the infection. The epidemic which appeared at Bay Ridge, Long Island, some years since was undoubtedly due to this cause; vessels were strung along the Long Island shore to ride out a specific detention until the whole fleet was thoroughly infected and the disease passed readily to the mainland. It is this practice of detention which in the past has contravened the interests of shipping and commercial men and has kept up a chronic warfare between merchants and quarantine." So far as the United Kingdom is concerned the uselessness of quarantine is obvious from the fact that yellow fever is purely a tropical disease and is found as a permanent disease—that is, lasting all the year through and becoming sometimes epidemic even during the cold season—only in those regions where the mean winter temperature amounts to at least from 68° to 72° F.[10] The fact, however, that a low temperature, while preventing the extension of the disease, does not destroy the germ, which may remain latent, developing again under suitable conditions, only emphasises the importance of dealing early with the seat of infection. Of this on board ship there exists many proofs. Yellow fever has practically always been carried by means of shipping, and this has been due to the actual infection of the vessel and not to the contagion from infected persons. As an instance of the slight amount of danger from the latter source Sir John Simon, in his eighth report to the Privy Council, mentions the fact that "during the epidemic at Lisbon in 1857 thousands of persons fled far and wide into surrounding districts; among those who thus fled numbers were already incubating the disease, and of course fell ill with it in their respective places of refuge more or less distant from Lisbon. In 182 cases of this description the Portuguese Government caused inquiry to be made whether persons about the sick fugitives had shown any signs of the infection, and the answers were that in no single case had this occurred."

With cholera, the only other disease against which quarantine is now directed, the case is quite as strong. It is quite unnecessary to adduce any proof of the non-contagious nature of the disease. In the fæces, and in the fæces alone, lies the infective germ, the comma vibrio, and this being capable of existing independently in water for a certain time is by means of this fluid conveyed freely wherever the sanitary conditions are such as to render possible the specific contamination of a supply common to a large number of persons. Wherever the water-supply is itself pure and protected from specific contamination an outbreak of cholera may be regarded with equanimity—it can be controlled and dealt with. The admission of cholera patients into general hospitals (while not advisable on account of the difficulty of dealing with the excreta) is a common practice, and there is no evidence of this having been productive of harm. There is, further, no authentic proof of the disease having been conveyed by merchandise or clothing, except where this has been actually soiled with the bowel discharges of infected persons. Dr. Alison mentions his experience as demonstrator of anatomy at Glasgow to prove that the disease cannot be communicated by means of the bodies of those who have died from the disease. He states that during the epidemic of cholera in 1848-49, when nearly all the subjects for dissection had died from cholera, not a single student suffered from the disease. In Paris during the outbreak of cholera in 1866 it was stated that not 1 of the 300 washerwomen employed by the Bureau de l'Assistance Publique was attacked, and that only 2 out of 911 men employed to conduct the funerals suffered.

Generally, then, of the three diseases—cholera, yellow fever, and plague—against which quarantine was directed not one can be considered as a contagious disease, although this was the main argument upon which the system was based. Much of the opposition to the abolition of quarantine has undoubtedly arisen from the fact that there was a strong interest for upholding the theory of contagion. The abolition of the system would have the immediate result of depriving a large number of persons of their means of obtaining a livelihood and of putting an end to the large revenue derived from fees and taxes. Hence, pressure was put upon quarantine medical officers to continue to advance views of pure contagion. M. Frank writes: "Let no one who declares the plague not to be contagious be allowed to exercise any public functions connected with this calamity; if there be such a functionary dismiss him."

2. That when carried out as strictly as possible quarantine had not had the effect of arresting the importation of disease.—The whole history of quarantine is a series of illustrations of its futility and proves it to be, as Sir John Simon so graphically described it, an elaborate system of leakiness. Theory must give way to practice, and the real test of quarantine as a system to be relied upon by the Government of a country for its protection must eventually be that of actual experience. As soon as investigation was made into the facts it was extraordinary how little evidence there was of the value of the system for the purpose which it was intended to serve. Dr. Colin[11] quotes the case of Civita Vecchia and says: "I could satisfy myself of the immunity of the port at a time when cholera prevailed at Leghorn, Naples, Ancona, and Sicily, everywhere imported by communication by sea; this immunity was entirely due to the rigorous and lengthy quarantine imposed upon all passengers from suspected vessels." Doubtless there was much force in this statement, inasmuch as the prospect of detention for a minimum of twenty-five days when a case of cholera had occurred on board had naturally the effect of putting a stop to all the Mediterranean trade. No one has ever attempted to prove that absolute cessation of intercourse with an infected place would not tend to arrest the disease. Putting all other considerations such as commerce and the interests of nations aside, it is obvious that total prohibition or an effective quarantine, though it might ruin a country, would doubtless prevent the importation of disease. "Compare with this the numerous visitations which Algeria has suffered (always imported from France) owing to the insufficient sanitary (quarantine) establishments along the coast. In marked contrast to the experience of this country was the immunity of the Balearic Isles in 1849, the immunity of Sicily in 1865-66 (until the arrival of the infected troops to put down the insurrection there), and the immunity at the same period of the islands of the Archipelago, and, lastly, the immunity in 1880 of the Turkish ports in the Black Sea in consequence of the quarantine restrictions against all arrivals from Russian ports."

But it must be borne in mind that the incidence of epidemic disease has always been most uncertain and in many cases inexplicable owing to the absence of exact information. In every epidemic it has been observed that certain localities and ports, though enjoying the freest communication with infected places, have remained exempt, so

that the mere fact of the escape of any one place in any given epidemic cannot be accepted as proof of the efficiency of quarantine. To explain the position of this country with reference to quarantine Dr. Colin says: "There are countries in which, notwithstanding their freedom of international intercourse, cholera seems to be with difficulty imported. Such is England, which seems to enjoy to a certain extent the privilege of continuing in epidemic seasons its commercial relations with impunity. There is nothing extraordinary in this, and it would be dangerous to infer from partial immunities the inutility of quarantine measures against cholera in all places. England knows pretty well that she owes her preservation to her geographical position." Unfortunately, however, from some points of view—though, perhaps, in the main fortunately—the immunity of England from the importation of cholera is by no means a fact, as her repeated outbreaks in 1848-49, 1853, and 1866 clearly show. Quarantine as practised in this country was found useless in the epidemic of 1831-1848, and was therefore abandoned. Spain and Italy have never succeeded in escaping any cholera epidemics, although it is in these countries that quarantine has been most rigorously carried out. During the Crimean War, as previously mentioned, quarantine was practically in abeyance; and in 1854, when cholera was raging in England, there was free intercourse between Gibraltar and Malta and also between those places and the Mediterranean, Black Sea, and Bosphorus. During the whole of the war, although vessels were landing sick at Gibraltar and Malta with no other precautions than their immediate isolation in hospital on shore, no spread occurred at either of those places. At the same time strict quarantine was kept up in other countries and failed to protect them. To give another instance, in 1855 a steamer arrived at Constantinople from Marseilles with a soldier suffering from diarrhœa, from which he eventually died and was buried at sea. On arrival at Syra, although there was no sickness on board of any kind, the vessel was declared to be infected and placed in quarantine, the passengers being landed for a period of ten days. Nevertheless, in spite of this rigorous quarantine, Spain and Portugal both suffered very severely; Lisbon especially was heavily visited with cholera in 1856 and by yellow fever in 1857 and 1858. Dr. Choppin, the President of the Board of Health of Louisiana, says: "We in Louisiana, acting under a quarantine law not absolute in its restrictions, after an earnest effort in executing it, conducted with all the honesty and energy at our command, assisted by incorruptible officials, have utterly failed in preventing the importation of the pestilence, which has thrown gloom and sorrow over the whole of the south-western valley."

THE CARDIFF INFIRMARY.—The annual general meeting of the Governors of the Cardiff Infirmary was held on Feb. 26th. The number of in-patients admitted during 1896 was 1570, as against 1408 in 1895. The average number of beds occupied was 117·77, against 107 35 in 1895. The average cost of each bed was £50 1*s.*, the cost in 1895 being £54 8*s.* 11,908 out-patients had been attended, an increase of 285 over the previous year. The total receipts for the year had been £6596 and the expenditure £6843. The last year's deficit of £1200 had been reduced to £277.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—A reception was given by the President, Dr. Sims Woodhead, and the council on March 5th at the Temperance Hospital, Hampstead-road, N.W. There were exhibits of x rays, the phonograph, microscopes, &c., performances by the Enfield orchestral band, and part songs. Readings were given by Mr. Vezey Strong and Dr. Ridge. The President, in opening the proceedings, said that he felt how unworthily he should fill the place of the late Sir B. W. Richardson, under whose able leadership the association had attained such great success. Alcohol should only be given when nothing else would do as well and in the same way as any other drug. Experiments had lately been made in America which showed that animals to whom alcohol was given were more easily invaded by the organisms of pus and anthrax, and this agreed with the experience of cholera epidemics in which those who took much alcohol were more liable to be attacked and to succumb. A statement as to the continued progress of the association was made by the hon. secretary, and short addresses were given by Dr. Heywood Smith and Dr. Hingston Fox.

ON

THE PATHOLOGY OF THE LYMPHADENOID STRUCTURES.[1]

Delivered at the Royal College of Surgeons of England on March 1st, 3rd, and 5th, 1897,

BY W. G. SPENCER, M.S., M.B. LOND., F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS AND THROAT DEPARTMENT, WESTMINSTER HOSPITAL, AND LECTURER ON PHYSIOLOGY AT WESTMINSTER HOSPITAL MEDICAL SCHOOL.

LECTURE III.[2]

Delivered on March 5th.

ILLUSTRATIONS OF THE LOCAL COMMENCEMENT OF LYMPHADENOMA.

Conjunctiva.—Trachoma forms a common illustration of an infection producing lymphadenomatous nodules. Lymphadenoma may occur in the eyelids. A boy had growths of the orbit and of the parotid region with leucocythæmia (Fröhlich).[3]

Nose.—In the nose overgrowth of the mucous membrane covering the inferior turbinals is very common, the result of local irritation. Occasionally it forms the starting place of a lymphadenomatous growth—e.g., in a case described by Rosenberg,[4] which became generalised, and death occurred in two and a half years from the commencement.

Tonsil.—On account of local irritation this organ is constantly seen in a condition of overgrowth. It may assume a malignant form, projecting as a tumour, capable at first of being shelled out, or extension may take place to the deep glands of the neck[5] or by rapid infiltration into the surrounding tissues of the fauces and pharynx.[6] Lymphadenoma may start in the tonsil, and after involving the glands in the neck become generalised.[7]

Pharynx.—Adenoid vegetations, a local overgrowth, is the common result of irritation. Occasionally a case commencing in this way spreads so as to involve the pharynx and larynx, and then become generalised (Chiari).[8] General hypertrophy of the fauces and pharynx is not uncommon, consisting of a simple overgrowth; cases, however, like those of Störk[9] are of a more malignant type, rapidly infiltrating the whole wall, causing anæmia, hæmorrhages, &c.

Larynx.—Measles and other infectious diseases may leave behind a hypertrophic laryngitis due to overgrowth of lymphadenoid tissue. In a case described by Stieda[10] there was found post mortem a general swelling of the ventricular bands and epiglottis with lymphadenoid tissue, also a general enlargement of the lymphatic glands and follicles.

Stomach and intestine.—It is well known that certain infectious diseases markedly affect the lymphadenoid tissue of the alimentary canal, especially the solitary and agminated follicles such as typhoid fever, anthrax, and the enteritis of swine. Less well known are the inflammatory changes in the intestinal follicles and the mesenteric lymph glands in diphtheria. In children after death from typical laryngeal diphtheria requiring tracheotomy Colman[11] found marked hyperæmia and enlargement of all the solitary follicles and Peyer's patches and mesenteric glands, no diphtheritic

membrane or bacilli or ulcerations being present. The cases of lymphadenomatous disease of the stomach and intestine have been collected by Newton Pitt[12] as follows: (1) A local tumour; (2) congestion and ulceration from hæmorrhage with leucocythæmia; (3) a new growth arising in the mucous and sub-mucous tissue and projecting into the lumen, especially from the lymphadenoid follicles in the cæcum and appendix; and (4) a widespread overgrowth infiltrating the coats of the bowel and forming a kind of sheath, leading to constriction or paralytic dilatation. No doubt in a number of cases it is difficult to know when the disease commenced, and, on the other hand, owing to early obstruction or perforation or other complication, the disease may never have time to become widely generalised. (Moore,[13] Hadden).[14] Yet all kinds of extension to the glands spleen, &c., are met with. A frequent origin of the condition is the chronic intestinal catarrh of children, in which, however, tubercle and lymphadenoma are difficult to distinguish. In some cases there has been distinct evidences as to causation. In Taylor's[15] case lymphadenoma of the small intestine followed upon typhoid fever. Coupland's[16] case of malignant lymphadenoma of the stomach was preceded by dyspepsia and inflammation of the bowels. The disease extended to the retro-peritoneal glands, then to the kidneys, ovaries, thyroid, and intra-muscular tissue of the thigh.

Bronchial and posterior mediastinal glands.—In no place where it occurs is the local origin of lymphadenoma more clearly marked. The very fact that it is so frequently found along with some signs of tuberculosis in the lung shows that although not of tuberculous origin it is much of the same kind. Another sign of preliminary excitation is the black pigment contained in the growth. The over-growth not only includes the actual lymphatic glands, but also the lymphadenoid tissue around the bronchi. The growths may rapidly compress the air-tubes and prove fatal before such extension. Yet when it happens to compress the lungs rather than the bronchi much greater extension may occur. Thus in Chaplin's[17] case after influenza—and this has been a common cause—dyspnœa and anæmia followed, and there was found post mortem a mass of glands around the bronchi extending into and infiltrating the right lung, whilst in the left lung were some caseating tuberculous nodules. The cervical, axillary, inguinal, and lumbar glands were enlarged, but not caseating. The spleen was characteristically lymphadenomatous. If we take three of Turner and Sutton's cases[18] we have instances of different types, but all three affording indications as to their primary origin. In a boy aged ten years there were cheesy masses in the apices of the lungs, enlarged mediastinal axillary, submaxillary, and inguinal glands, some hard, others soft, and the kidneys were enlarged and infiltrated, but not the liver and spleen. The boy had suffered from purpuric eruption, ecchymosis, and anæmia, clear evidence that there had been also leucocythæmia. A man aged thirty-six years, who had suffered from syphilis and had been addicted to drink, had caseous and fibroid changes in the lungs, a mass of glands compressing the right bronchus. He had had leucocythæmia and showed thrombosis of the iliac veins, embolism of the middle cerebral artery, and the spleen was enlarged with firm masses in it. A woman aged twenty-four years commenced by suffering from pleurisy and pericarditis, which were followed by faintness after food, morning retching, stabbing pain in the chest, and dysentery. The pleura and pericardium were thickened and, together with the right lung, infiltrated by greyish nodules, the bronchial, cervical, and lumbar glands were enlarged and softened, and the spleen, liver, and kidneys infiltrated by semi-gelatinous nodules.

The thymus.—The thymus is also the subject of lymphadenomatous enlargement, and this is clearly distinguishable from the condition of cystic and hæmorrhagic enlargement at birth by the fact that other lymphadenoid tissues are involved. Thus in a woman aged twenty-nine years there was great enlargement of the thymus along with a similar condition of the supraclavicular and axillary lymphatic glands (Brigidi and Piccoli).[19] In a child, aged nine years, besides the thymus, which formed the greatest enlargement, there was also enlargement of the spleen and the intestinal follicles, together with nodules in the liver (Eberth).[20] In the case of a woman who died shortly after removal of a goitre the thymus was found enlarged as well as the tonsils, both palatal and lingual, and the intestinal follicles (Schnitzler).[21] Virchow[22] said that he had seen a number of cases occurring in young recruits which began in the thymus. Of course, it is possible for a malignant tumour to begin in the thymus and yet not be lymphadenoid in character, as in the case described by Rolleston of a hæmorrhagic adeno-chondro-sarcoma, the glandular portion having the appearance of being derived from mucous glands like the parotid; the tumour in this case clearly grew from remains of the primary thymus to which Hassall's corpuscles belong. The growths in the thymus and anterior mediastinum are usually fatal at an early period before much generalisation has occurred owing to tracheal and bronchial pressure.

The axilla.—Chronic enlargement of the lymph glands from irritation entering the lymphatics from the hand and also from the breast may be found tuberculous on exploration. In other cases it may be recognised as the starting-point of lymphadenoma. I have had two cases under my care lately in both of which the enlarged glands were certainly neither tuberculous nor malignant. They showed on section lymphadenoid fibrous tissue, and portions had so intimately ensheathed the bloodvessels as to be irremoveable.

Neck.—Lymphadenoma frequently commences in the neck. In some cases it is possible to assign a cause, such as a carious tooth, a purulent discharge from the ear, and repeated inflammations of the tonsils. It may start as an acute or sub-acute glandular inflammation, something like mumps,[23] which suggests a specific cause reaching the glands by the lymphatics. It is most difficult to distinguish from tubercle except by the tendency to caseation on the part of the latter. As I have before mentioned, this caseation is absent in the diffuse form. I have had lately a man under my care with enlargement of the glands on both sides of the neck of an indolent character. As arsenic was of no avail I removed some. There was no evidence of caseation, but from the microscopical structure the appearance was either that of diffuse tubercle or an endothelial new growth, but the latter was excluded by the time the disease had lasted. A case of lymphadenomatous glands in the neck which I have long had under view is interesting as standing intermediate between a local and generalised lymphadenoid. A middle-aged man was under my colleague Dr. de Havilland Hall with a lymphadenomatous mass in the neck. For some time arsenical treatment kept the growth in check. Later, enlargement continued in spite of the treatment, and I removed all that I could of the growth, leaving some masses about the large vessels in the root of the neck. After the operation he was again put on arsenic, and although the lymphadenoma has never quite gone it has for some years not advanced. Unfortunately, the man cannot continue a course of arsenic very long without sickening of the drug and then he has to rest awhile. The most malignant form of lymphadenoma may commence in the neck. A girl (under Durham[24]) first felt the neck stiff and tender after sleeping in a damp bed. The enlargement commenced below the jaw, soon ulcerated, and then formed a large oval ulcer, infiltrating the muscles of the neck. After death an enlarged mass was found surrounding the upper part of the abdominal aorta behind the stomach and pancreas, involving the mesenteric and lumbar glands.

The groin.—The groin is not uncommonly the starting place of lymphadenoma of various forms. Sometimes evidence of previous source of irritation is found, such as venereal disease, strain, or septic absorption from the leg. A chronic indolent enlargement is seen in hot climates, of obscure origin, sometimes called malarial. As compared with the gland in the neck the rarity of tubercle is remarkable, and on this account the diagnosis of lymphadenoma is made easier. I saw, however, not long ago a young man who had been put under an anæsthetic in order to remove a mass of glands supposed to be tuberculous. The operation was not begun owing to enlargement of iliac and lumbar glands being discovered. I suggested the administration of

Hosted by Google

large doses of arsenic, and the glands both in the groin and in the lumbar region quickly subsided. Unfortunately, however, lymphadenoma of the groin has a very great tendency to become generalised and to show malignant characters. In Taylor's [25] case the lymphadenoma commenced as a lump in the groin, and this was followed by swelling of the leg, general enlargement of the lymphatic glands, especially those of the parotid and sub-maxillary regions, and was attended by fever but not by leucocythæmia. The liver was found at the post-mortem examination to be enlarged, but not the spleen. On the other hand, in Greenfield's [26] case, the spleen, lungs, and skin were affected from a growth in the groin, but not the other lymphatic glands. The lymphadenoma may remain local, but infiltrate most widely around after a malignant fashion. In Lediard's [27] case there had been a lump in the groin for three years, then it ulcerated and formed a bleeding mass, which caused extreme anæmia accompanied by fever and vomiting. No other growths were discovered post mortem. In Morton's [28] case the enlargement began symmetrically and simulated at first chronic recurrent inflammation. Later, the growth extended and infiltrated the muscles of the abdominal wall and surrounded the large vessels. The lungs were found studded with secondary growths. There are, however, many cases of lymphadenoma in the groin which are not malignant in the earlier stages, and which either yield to drugs or admit of removal. Even when the lumbar glands have been enlarged behind the peritoneum they have been successfully shelled out (Marconi).[29]

The spleen and bone marrow, especially the former, are involved when lymph-adenoma becomes generalised, and hence there are endless varieties of combinations with enlarged lymph glands and with leucocythæmia.

Spleen.—The commencement of lymphadenoma in the spleen is very questionable. The cases in which the spleen is the chief organ involved are mostly diseases which have in all probability entered through the alimentary canal, or are due to some other general infection through the circulation. Enlargement of the spleen is common in young children and sometimes seems due to nothing more than bad feeding. Upon suitable nourishment and arrest of intestinal catarrh the spleen subsides. However, if the case is not taken early generalised lymphadenoma soon sets in with anæmia, leucocythæmia, and enlargement of lymphatic glands and follicles. Malaria and malarial affections are another common source of lymphadenoma; the spleen remains enlarged after the malaria has subsided. Wilson [30] has recorded cases occurring in three generations of the same family in which there were enlargement of the spleen and anæmia, but without leucocytosis or enlarged lymph glands. There is considerable practical importance in the distinction because a spleen enlarged simply as the result of malaria has been frequently removed with success. On the other hand, all cases of splenectomy in generalised lymphadenoma with leucocythæmia have failed. The changes produced in lymphadenoma in the spleen are of two kinds. In one form the Malpighian bodies stand prominently out as white or yellowish masses, which are hard to distinguish from tubercle. In other cases the enlargement is of the diffused variety, soft when the overgrowth is mainly of lymphadenoid tissue, hard when mainly of connective tissue from the capsule and septa. This latter form also contains much pigment and is difficult to distinguish from a spleen the result of malaria. In cases of lymphadenoma accompanied by leucocythæmia the spleen, besides being much enlarged, is liable to wedge-shaped infarcts. The local enlargement of the spleen occurring by itself, having no obvious connexion with any affection of the other lymphadenoid tissue or with the blood, has been called primary splenomegaly. The growth is slow, and cases have been submitted to splenectomy successfully. It is not very clear, but apparently it is the cells of the splenic pulp which multiply and compose them. The interest lies, then, in the slow and local growth of the primary tumours. In this respect it may be compared to some of the tumours of bone.[31] The carcinomas and sarcomas of the spleen are secondary growths.

Bone marrow.—It is in generalised lymphadenoma that the bones are affected, but there is this marked distinction, that beyond the change to lymphoid marrow the bones show only tenderness, temporary swelling of the soft parts, and pain. There is no enlargement like the spleen. In such cases the spleen is always enlarged, very often all lymphadenoid structures, and there is leucocythæmia. I doubt very much the existence of the so-called "pure myelogenic leucocythæmia." Returning now to the new formations allied to lymphadenoma. A simple circumscribed tumour may commence and grow slowly, without at first causing any marked enlargement of the bone, but rather replacing the bone framework and the marrow cavity by a very delicate, moss-like bone. Owing to the absence of a distinct enlargement notice may first be drawn to the growth by the occurrence of a spontaneous fracture owing to the replacement of the bone by the tumour. In structure the growth consists of small, round cells with a variable amount of newly formed connective tissue into which hæmorrhages may occur. In other cases the tumours are multiple in one or many of the bones of the skeleton, appearing as discrete tumours through which the knife easily cuts, or undergoing secondary changes resulting in hæmorrhages or cyst formation, or pathological fractures (Herrick and Hektoen,[32] Kahler [33]). Generalisation takes place in some cases very early and in others only late. These generalised forms connected especially with bone marrow assume three types—one approaching cancerous osteomalacia, one approaching osteitis deformans, and one in which leucocythæmia is the prominent feature. But in all there is some enlargement of lymphadenoid tissue in the lymphatic glands, spleen, &c. Nothnagel's case [34] was of an osteomalacic type. Pain began in the sternum and was attended by wasting, sweating, and irregular fever. The pain spread to the bones of the trunk and extremities, besides which there was anæmia, swelling of the spleen, and enlargement of the lymphatic glands, but there was no leucocythæmia. The bones especially affected were the scapula, clavicle, ribs, vertebræ, sternum, pelvis, and the metatarsal and metacarpal bones. On post-mortem examination the fatty marrow was found to have been replaced by greyish-white material interspersed with long septa. The tissue consisted of small round cells and contained blood pigment. On maceration the bones appeared of a spongy material like moss which had filled the marrow cavity. Moore, Hammer, and Goodhart's cases are closely related or show intermediary stages with osteitis deformans. In Moore's [35] case the skull was infiltrated by small round cells and the cervical lymph glands were enlarged. In Hammer's [36] case the skull and vertebræ were much thickened and the spleen and lymphatic glands were enlarged. Goodhart [37] described a typical case of osteitis deformans with nodules of lymphadenoid material in the spleen, liver, pleura, and in the mediastinal and abdominal glands. Leucocythæmia was a prominent symptom in the following cases. A woman suffered from symptoms of anæmia, erythema nodosum, and rapid cachexia. At first she had amenorrhœa and then profuse uterine hæmorrhages. There was great tenderness of the sternum, the ribs were slightly tender, and the red corpuscles were to the white as 5 to 1. At the post-mortem examination there were many small hæmorrhages, but no enlarged lymphatic glands. The spleen weighed 10 oz. The skull cap was very heavy and dense and the cavity of the femur was full of red lymphoid marrow (Beatty).[38] Grawitz [39] described a similar case which he called malignant osteomyelitis attended by marked anæmia and metastasis. In Zahn's [40] case there were lymphatic tumours with softening of the bones, curvature

of the vertebræ, and spontaneous fractures of the ribs. In Weber's[41] case, a man aged forty years, who had had syphilis, died exhausted after one and a half years' illness. The sternum was enlarged and bent with the ribs so as to compress the aorta, and these bones with the vertebræ contained reddish tissue. The cranium had many rounded spots the size of a threepenny-piece. There was amyloid degeneration in the kidneys and spleen. The new tissue consisted of small round cells. Comparable to the primary tumours of the spleen called splenomegaly, are the well known giant-celled myelomas or myeloid sarcomata, which grow from the marrow at the ends of the long bones and in the short and flat bones. But as distinguished from the small celled myelomas or lymphadenomas of the bone-marrow above noted they show no tendency to involve the other lymphadenoid tissues. A further resemblance between the spleen and marrow is to be found in the fact that carcinomas and sarcomas of the bone-marrow are likewise secondary growths.

THE COMPLICATIONS WHICH ATTEND LYMPHADENOMA.

Fever.—Any form of lymphadenoid enlargement may be attended by fever the result of cell destruction and of the absorption of the products. The characteristic fever of tonsillitis and other glandular affections, of typhoid fever, malaria, and relapsing fever are well known. In cases of generalised lymphadenoma a fever of the continuous or intermittent type, but generally irregular, occurs, and is accompanied by profuse sweating and general exhaustion.

Leucocythæmia and anæmia.—I have already referred to the fact that an excessive production of white cells provokes destruction of red cells and also intravascular coagulation. Infarcts occur especially in the spleen, the capillaries of mucous membranes and of the cerebral arteries, &c., become choked with white corpuscles, and ulceration and hæmorrhages ensue. The patient may die from recurrent epistaxis, cerebral hæmorrhage, perforation, &c. Fatal cerebral hæmorrhage may thus occur in young patients.

Fatal results of the pressure of lymphadenomatous masses.—Growths in the mediastinum press on the trachea and bronchi. The stomach or intestines may be compressed, intestinal obstruction ensue, or absorption by the lacteals be prevented. The heart and large bloodvessels may become surrounded by a solid mass which impedes the circulation. Compression upon the arteries, veins, and lymphatics affects important organs such as the liver and kidneys. Moreover, these organs may be infiltrated diffusely with small round cells which compress the actual gland cells and cause them to degenerate, so that the function of the gland may easily be much more impaired than the external appearance of the organ might lead one to suppose.

Lymphadenoma in animals.—The various forms of lymphadenoma are met with also in animals. I had a cat which suffered from marked anæmia and leucocythæmia; its spleen weighed one-tenth of the whole animal, whereas the spleen of a normal cat weighed on the same day was only $\frac{1}{170}$ part. A dog I examined had a lymphadenomatous mass which began in the posterior mediastinal glands and compressed the trachea and bronchi. A similar mass in another dog arose from the præ-vertebral abdominal glands and surrounded the lower end of the aorta and the iliacs. Reinländer[42] has noted lymphadenoma with leucocythæmia in the horse.

Lymphadenoma in relation to tubercle.—There must be some close connexion between lymphadenoma and tubercle, for in the majority of post-mortem examinations some distinct tuberculous lesion has been found and in many it has been impossible with the naked eye to distinguish what is lymphadenomatous from the tubercle. The absence of caseation is no disproof of tubercle, nor does the absence of giant cells on microscopical examination exclude the diffuse form of tubercle. The inoculation test is also liable to several fallacies—e.g., if both tubercle and lymphadenoma be present the tubercle bacilli may easily get into the blood or lymph passing through a lymphadenomatous mass. There appears also another similarity in these mixed cases of lymphadenoma and tubercle; both affections appear to start from the same place, whether this be through the throat, neck, lungs, or intestines. One of the first cases of lymphadenoma of which I have notes was that of a young man who came to St. Bartholomew's Hospital under Mr. Willett. I incised some tuberculous glands in the neck. He soon died with pulmonary œdema and bilateral hydrothorax. The heart and large vessels were enclosed in one mass of lymphadenoma and there were also masses in the abdomen. Besides the difficulty as to glands, it is easy to confuse lymphadenomatous masses in the lung with tubercle surrounded by hepatisation. The masses in the spleen, sometimes compared to suet in a pudding or to the almonds in toffee ("hardbake"), are due sometimes to lymphadenoma, sometimes to tubercle. Cases by Dietrich,[43] Fischer,[44] Cordua,[45] Ricker,[46] Brentano and Tangle,[47] Tooth,[48] Macnamara,[49] and Dickinson,[50] in addition to many writers already named, afford abundant evidence of the frequency with which these two effects occur together and of the difficulty in distinguishing them. The recent epidemics of influenza, besides causing tuberculosis, have in a number of cases started generalised lymphadenoma.

Lymphadenoma and syphilis.—The connexion is at any rate only an indirect one. Lymphadenoma has frequently started from a chronic, indolent, enlarged gland in the groin which may have been due to previous venereal infection. Again, where generalised lymphadenoma appears in a patient who has suffered from syphilis it may be thought that the latter has predisposed to the former (Guttman).[51] The success of the local application or internal administration of iodine or iodide of potassium cannot be held to indicate the syphilitic origin of the enlarged glands. Wunderlich saw masses of enlarged glands which he regarded as lymphadenoma disappear under iodide treatment in cases in which, he said, syphilis could be excluded. Hutchinson,[52] after describing the disappearance of large masses of glands, did not attribute the good effect of the iodide to the fact that syphilis was the cause of the enlargement, but says that it is interesting that any form of lymphadenoma should yield so readily to the iodide treatment. A woman still under my care had a characteristic mass of lymphadenoma on both sides of the neck which was extremely hard. The disease did not improve under arsenic alone; I then administered iodide internally and applied an iodide ointment externally, and this has been followed by a gradual disappearance of the glands. Before doing so I made an exploratory incision at one place which was exceedingly hard and painful; and in order to exclude tubercle I cut out a piece of tissue, which under the microscope was found to consist of sclerosed gland tissue with thick-walled vessels.

Lymphadenoma and its treatment by arsenic.—It is well known that arsenic is a most valuable drug in the treatment of lymphadenoid diseases, so that the benign and the malignant forms are often distinguished by the success or failure of the arsenical treatment. But the success or failure of the drug depends upon circumstances. The treatment must begin before complications have arisen; large doses are generally required. One preparation of arsenic will act better on, and be better borne by, one patient than another. Katzenstein[53] has described his success in "leukæmia lymphatica et splenica," accompanied by anæmia and cachexia, to the subcutaneous administration of arsenic. Liquor arsenicalis may be injected into the back or directly into the tumour. Touton[54] has described a case of general "sarcoma of the skin of leukæmic or pseudo-lukæmic origin" which was cured by arsenic. In Butlin's[55] case there was a bilateral affection of the testicle with nodules in the skin. The growths subsided under arsenical treatment. I saw a woman in St. Bartholomew's Hospital under Mr. Willett who had had both breasts removed in the country for malignant disease. The axillæ and infra-clavicular fossæ were one mass of enlarged glands. The whole subsided under arsenic, and presumably, therefore, the tumours of the breast would have done the same. I have already

referred to a case in which arsenic was successfully administered after the growth had been partly removed. One should not adhere to the surgical rule which obtains in carcinoma and sarcoma, that removal is only permissible when all the disease can be taken away. Partial removal followed by drug treatment is attended by success and prevents the disease from becoming generalised.

CONCLUSION.

I have noted in the course of these lectures some of the chief features exhibited by diseases of lymphadenoid structures; we may with confidence look forward to an increase before long of our knowledge, especially in two directions. Besides the organisms to which I have already referred to as known causes of lymphadenoid disease many observers have found organisms in lymphadenomatous growths. The results are not yet sufficiently in agreement for any opinion to be formed at present; the organism most frequently seen has been the staphylococcus aureus. There are a number of clinical observations on the effect of administering materials obtained from the thymus, spleen, and bone marrow, and some have been successful. With a greater knowledge of the infection we shall be better able to estimate individual differences in resistance and so obtain more light on the varieties of generalised lymphadenoma. Meanwhile we must base our treatment on the closely allied conditions produced by tubercle and syphilis. Excision of the disease where the conditions are favourable, and the administration both locally and internally of arsenic and iodide in full doses, will be attended by success when undertaken at an early stage, except against the most malignant cases. The treatment of the anæmia is the other important point, and is worthy of more relative attention than the leucocythæmia. Thus an improvement has followed upon the administration of oxygen[56] in cases of lymphadenoma, the diminished number of red cells being assisted in exchanging carbonic acid for oxygen by the large supply of the latter.

ILLUSTRATIVE CASES OF APHASIA.

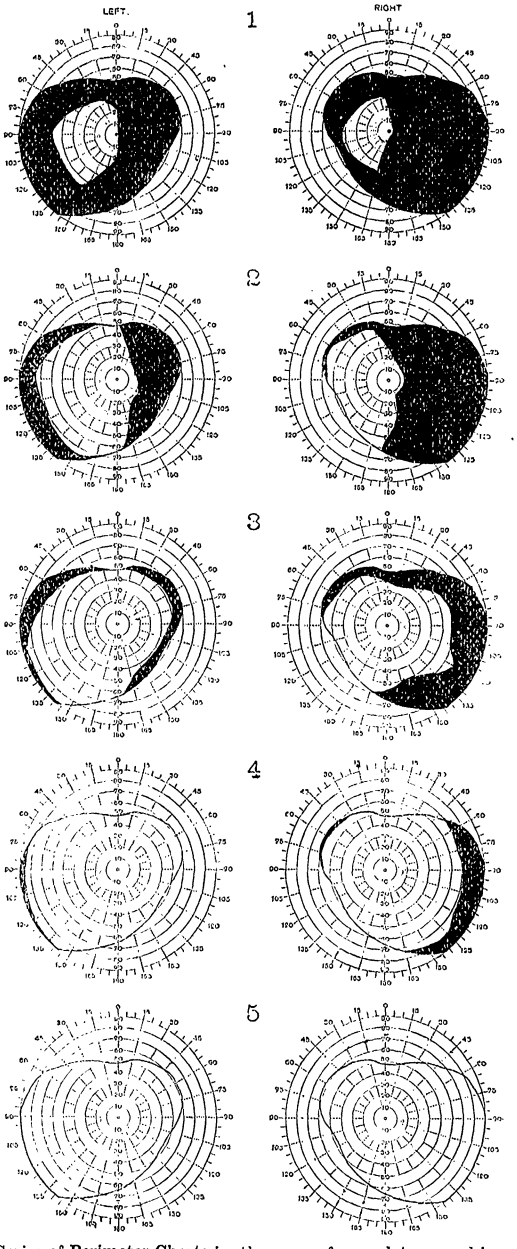
BY BYROM BRAMWELL, M.D., F.R.C.P. EDIN., F.R.S. EDIN.,

ASSISTANT PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, SCHOOL OF MEDICINE, EDINBURGH, ETC.

CASE 1. *Clinical remarks on a case of complete agraphia and almost complete word-blindness, with right-sided bilateral temporal hemianopsia, due to a lesion (gumma) in the region of the left angular gyrus, in which rapid and complete disappearance of all the symptoms took place under the administration of large doses of iodide of potassium.*—The case to which I wish to direct attention is one of very great interest. When first seen the patient was suffering from complete agraphia and word-blindness, with right-sided homonymous hemianopsia and slight optic neuritis. The word-blindness, hemianopsia, and optic neuritis have now entirely passed away and she is able to write as well as she has ever been able to do. In short, under the administration of large doses of iodide of potassium an extraordinarily rapid and complete cure has taken place. I will in the first place give the full clinical history, and then discuss some of the more important points.

Clinical History.[1] — A. B., a widow, aged thirty-four years, was admitted to Ward 5A of the Edinburgh Royal Infirmary under my care on Nov. 14th, complaining of severe pain in the head, dimness of vision, and general stupidity. The patient stated that she had suffered from her head since the harvest time. The headache came on suddenly about the middle of September. She attributed it to stooping in the hot sun while working in the fields. The pain was not continuous; ever since its commencement it had been worse at night. Three weeks before admission her eyesight became affected; the dimness of vision was rapidly developed. The patient stated that since her illness commenced she had felt "stupefied"; she felt as if she "were in a mist," not knowing exactly where she was or what she was doing. She definitely stated that from the commencement of the attack she had no difficulty in understanding what was said to her, but that she had some difficulty (hesitation and slowness) in answering questions put to her by her friends. She further stated that since her illness came on she had lost the ability to read and write. Before the attack she was a good reader, but her writing was never good, for she had never been to school. Her memory was, she said, very defective; she expressed it as "almost gone." She stated that with the exception of exposure to the sun she knew of no cause for her illness; she had never received any head injury. The patient stated that she had always been a strong, healthy woman and that she had never had any serious illness until the present trouble commenced. Her husband died abroad about five years previously. She had had two children and two miscarriages. The first, a girl, born at the full time, was stillborn. The second, a girl, born at the seventh month, lived for about two hours after its birth. The third and fourth pregnancies ended in abortions. This history was, it will be observed, highly suggestive of syphilis. She had no living relatives. She did not know the cause of the death of her parents—in short, she could give no information regarding the family history.

She was a fairly well-nourished, dark-complexioned woman, with a dreamy look. *Nervous system.*—She was unable to give ready answers to many questions which she should have easily answered straight off. For example, in answer to the question "Where do you live?" she at first made no answer, but some minutes afterwards suddenly gave the address. The difficulty in answering questions was, she said, not due to any defect in speaking or to any defect in understanding what was said to her, but to want of memory. The headache, which was her chief complaint, was very severe, but not constant; it was, she said, of a boring and squeezing character and was most marked over the vertex and frontal bone. It was much more severe at night than during the day, and was sometimes aggravated, she said, during the day "by straining efforts to see with the right eye." She frequently clasped her head with her hands as if in pain, and when lying in bed burrowed her head in the pillows. There was no pain or tenderness on percussion over any part of the skull. There had been no vomiting, but the patient complained of giddiness. The pupils were equal in size, regular in shape and widely dilated; their reaction both to light and accommodation was distinctly sluggish. On ophthalmoscopic examination the edges of both discs were seen to be ill-defined and slightly swollen. These appearances were more marked in the left than in the right eye. There was, in short, a slight degree of optic neuritis. Perimeter measurements showed right-sided homonymous hemianopsia, with considerable constriction of the peripheral portions of the left side of the field in both eyes. (See Perimeter Chart 1, Fig. 1.) Central vision was unaffected and the patient could distinguish colours correctly. As regarded auditory speech, the patient could understand what was said to her perfectly well when she was first spoken to, but after a short time she became confused and stupid and her answers became hesitating or she failed to answer the questions which were put to her. The auditory-speech centre appeared, therefore, to be intact, but more easily exhausted than in health. Motor speech was normal, or practically so. At times she said she could not find the words she wished to use, but she never used wrong words except in naming objects. As regarded visual speech, she was quite unable to read anything except some individual letters and she was only able to recognise a few of these. After puzzling over single letters for a short time and naming some of them correctly she was unable to name any more. She had also difficulty in reading numbers. In short, there was a condition of almost complete word-blindness. She was unable to name many of the objects which were shown to her; she appeared to appreciate the fact that she was unable to name them and that she named them wrongly. (A more detailed report on this point will be given below.) There was complete agraphia. She could not write her own name; she could not write down any single letter; and she could not write to dictation any letter or word. With her right hand she could not copy letters or words; she made a very imperfect attempt to do so with the left hand. In short, the paths-



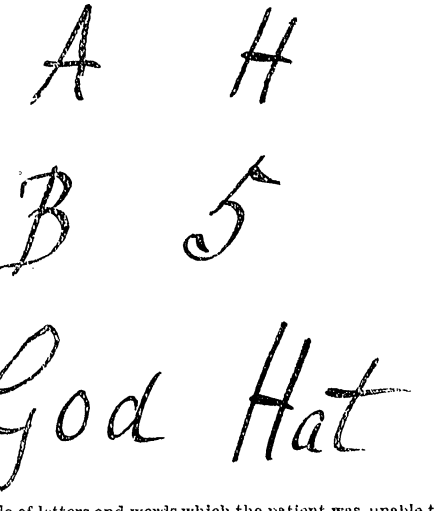
[56] Taylor: Transactions of the Clinical Society, 1895, vol. xxviii., p. 47.

[1] The detailed clinical history recorded in the text was elicited as the result of repeated short examinations. When the patient was first admitted to the hospital her brain power was so easily exhausted that it was only possible to elicit the facts gradually—a few at each examination.

Hosted by Google

from the visual-word centre to the writing centre seemed to be completely blocked. The path from the higher visual centres to the auditory-speech centre seemed also to be in some degree interrupted, because of her inability to name many of the objects which she certainly saw and (?) apparently recognised. I will explain my reasons for this

FIG. 1.

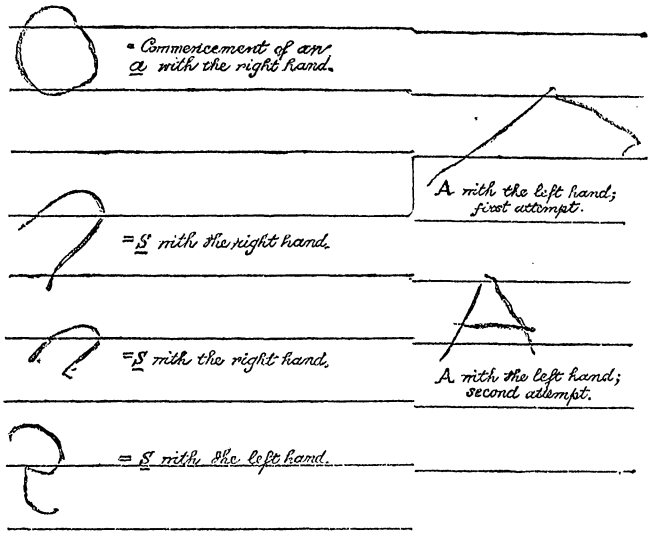


Series of Perimeter Charts in the case of complete agraphia and almost complete word-blindness, with right-sided bilateral temporal hemianopsia, described in the text. (The black area represents the blind parts of the fields.)
Chart 1 represents the fields of vision on Nov. 17th.
,, 2 represents the fields of vision on Nov. 24th.
,, 3 represents the fields of vision on Dec. 1st.
,, 4 represents the fields of vision on Dec. 8th.
,, 5 represents the fields of vision on Dec. 15th.

localisation later. I should here note that the patient was naturally right-handed. There was very decided difficulty in making movements with the right hand when the eyes were closed. For example, when told to touch the tip of the nose with the right fore-finger she more than once merely waved the hand in the air and never once succeeded in touching the tip of her nose without hesitation. She could, however, perform this movement, the eyes being closed, with the left hand. There was no paralysis of the right hand. The squeezing power, as tested by the dynamometer, was quite as good in the right as in the left hand. She was unable to appreciate slight differences in weights placed in the two hands. Unless the difference was very considerable, she always said that the weight which was placed in the left hand was the heavier. When there was a marked difference between the weights she recognised it correctly. Tactile sensibility was unimpaired. The patient complained of giddiness and walked in a hesitating, shaky manner, apparently the result of giddiness and defective vision. The motor and sensory functions were, except for the defects described above, quite normal. *Alimentary system.*—The tongue was pale, flabby, white, and moist. The bowels were constipated. *Circulatory system*—The first sound of the heart was very faint and weak, but there was no valvular disease. *Urinary system.*—The urine was pale amber-coloured and acid; its specific gravity was 1018, and it contained no abnormal constituents.

Treatment and its results.—On Nov. 14th (the date of her admission) ten grains of antipyrin were given when the headache was severe, together with a laxative each night. On the 15th, 16th, and 17th the patient's condition was unchanged. On the 18th the antipyrin was found to merely relieve the headache for the time, but produced no real benefit. She woke the previous night at twelve o'clock complaining of severe headache. During the greater part of the night she was tossing about in bed, holding her head with her hands, burying it in the pillows, and complaining of headache. Twenty grains of iodide of potassium three times daily were substituted for the antipyrin. The speech functions were carefully tested on this date with the following result. The patient understood everything that was said to her and answered questions with more facility (less hesitation) than she did on her admission. There seemed to be no defect either in the auditory-speech centre or in the motor-speech centre, but there was a decided want of sharpness and briskness in answering questions, apparently the result of the general mental dulness and slowness of cerebration which were present. There were marked word-blindness and complete agraphia. She was unable to name many of the objects which were shown to her. For example, when shown a knife she named it correctly; a pencil she termed a knife and fork; a bunch of keys she called knives; and a

FIG. 2.



Facsimile of letters and words which the patient was unable to read on Nov. 18th.

tape measure she could not name. She recognised and was able to name a pencil after it had been named to her, but almost immediately afterwards was unable to name it. She instantly recognised and correctly named a penny, a halfpenny, a sixpence, a shilling, and half-sovereign. (The lightning-like rapidity with which she named pieces of money, when contrasted with her slowness in naming almost every other object which was shown to her, was very remarkable.) She was unable to name a door key; she said, "Oh! I ken what it is, if I could only keep it in

Hosted by Google

mind." She called a book a knife, and a bottle of medicine a knife. She could not read (name) any of the following letters and figures: "a, o, b, h, e, 5, and 8"; and could not read any of the following words: "dog," "cat," "God," and "hat." (See Fig. 2.) She was unable to write any letter or word to dictation or to copy any of the letters or words which were used as test objects. On the 19th, when asked her name, she stated it correctly, but she could not write it. She was able to spell the word "dog," but could not write it. She correctly named (read) the letter "o," but could not write it; she could not write the letter "a." On this day she correctly read (named) the letters "b, a, h, o, s, and q"; but could not read the following words: "dog," "hat," "Edinburgh," and "Florence." When asked to read the word "dog" she said, "It has just went out of my head; I have forgot it, I think." On the 20th the patient named a pencil, bottle, book, watch, keys, knife, and wax vesta correctly. She said the letter "t" was "h." She named the letter "o" correctly, but could not copy it. When told to write the letter "o" she said, "Oh! I cannot mind." She put the pencil frequently up to her lips, moistened it, and then, after placing it on the paper, made an attempt to write, but could not write a single letter or word. When asked what the number 10 was she said it was "to"; when told it was a number she said, "Then if numbers it is one and nothing; that would be two." She said "r" was "q" and named the letters "m" and "s" and the numbers "20" and "17" correctly. She said "132" was "13," and "246" was "400," but read the word "cat" and her own Christian name, but not her surname, correctly. The patient slept well at night, and on the 21st she said "a" was "f" and "o" was "f"; named "f" and "m" correctly; said "i" was "o" and "s" was "t" or "i"; named a pencil correctly; said a knife was a pencil or a shooting-knife; and said a button-hook was a pencil. When asked if it was a button-hook, she immediately said, "Yes—a button-hook." She was unable to name a tuning-fork. When asked to name a bunch of keys she said, "I don't mind the name," and then said watch-key. She was unable to tell the time. When asked to write her name she spelt it correctly, but could not write it. She named the letter "a" correctly, but could not write it. Asked to copy the letter "a" with the right hand she could not do so. When a pencil was placed in her right hand and she was told to write one of her own names she made spaces on the paper corresponding to the letters, but was unable to write any single letter. She was able to trace the letter "o" correctly with her left hand; wrote the letter "A" with her left hand imperfectly, making a triangle, and after having written it said she thought it looked like "X"; succeeded in making an "A" with the left hand on a second attempt; and made an imperfect attempt to form the letters "B" and "S" with her left hand. When asked to make an "s" with the right hand she could not do so, and said she felt as if her "hand were going from her." She made an "o" with her right hand, but could not make "a" or "b" with her right hand. On being shown pictures she recognised and named correctly the following: pigs, sheep, cows, dog, child, pigeon, monkey, and kitten. She said a picture of hay and horses was a farmyard; geese were ducks; and a horse was a farmyard. She could not name a cart or trees. When shown the picture of a donkey she said it was an ass. Her ability to read music was not tested because she had never been trained to read it. On the 22nd the patient read better than she had done since her admission, but was totally unable to write spontaneously. She could copy many letters with her left hand, but was unable to do so with the right, and had the same difficulty in directing the movements of the right hand when the eyes were shut which has been already described. The dose of iodide was increased to thirty grains three times daily. She was given a light diet (milk, fish, &c.) and a nightly dose of cascara sufficient to produce a satisfactory movement of the bowels. On the 23rd the headache was better. Her mental condition was brighter. She named a knife, pencil, keys, and button-hook correctly. She called a tuning-fork "musical tongs." Her power of reading had greatly improved. She read correctly the following sentences: "In the animals' hospital"; "The invalids"; and "Page 88." When asked to spell her Christian name she did so correctly; but when told to write it she could not make a single letter. When asked to write the letter "a" she said: "That is an 'o' with a crook." She made an "o," but could not make the letter "A" with the right hand; she was also unable to write the letter "s" with the right hand. She wrote the letter "A" with the left hand after two attempts. It will be observed that at this stage of the case her mental conception of the form of letters seemed to be retained (or perhaps it would be more correct to say regained); for example, she said that the letter "a" was an "o" with a crook, but she was nevertheless unable to write the letter "a." In other words, she was able to recall the visual memory of the letter "a" (the memory of the visual picture of the letter "a" was

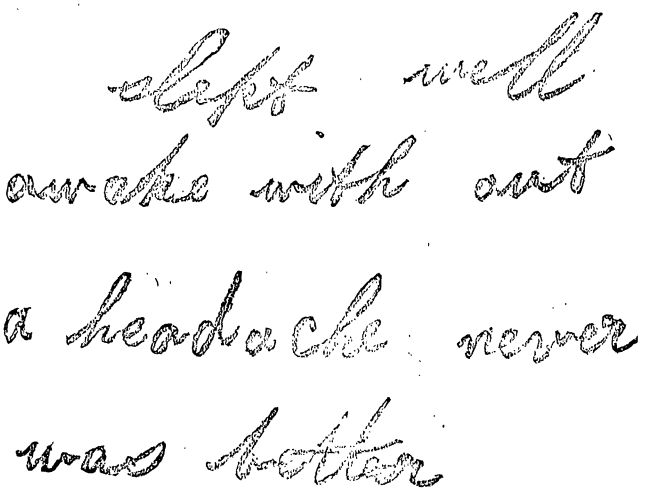


FIG. 3.

retained in the visual-speech centre which was acting so far as the cell group which represents the letter "a," at all events, was concerned), but she could not reproduce (in the motor-writing centre) the discharge required to produce the muscular movements concerned in writing the letter "a" (because the connecting fibres between the visual-speech centre and the motor-writing centre were still blocked by the lesion). In Fig. 3 facsimile illustrations of her writing

FIG. 4.

Facsimile of the report which the patient wrote of her condition on Nov. 27th.

(written with the right hand) at this date are given. On the 24th she slept fairly well. She on this date described the pain in the head as neuralgic in character, and said that it was much less than it had been. The constriction of the fields of vision was then markedly less than it was a week previously. (See Fig. 1, Chart 2.) She named correctly every object which was shown to her this morning; she was

Hosted by Google

also able to tell the time on a watch correctly (she had not been able to do so before); and she also wrote her own name and the word "cat" with the right hand. On the 27th she was very much better; she read to herself for the first time, and was able to write individual letters and short words with the right hand. She wrote the following report: "Slept well awoke with out a headache never was better." (See Fig. 4.) She had never been to school, and her writing and spelling were naturally very defective; she almost always spelt the word "slept" as "slepth," "slepteh," or "slepthe." When words were spelt to her she could write them down correctly. On the 29th the patient slept well and woke without a headache. She wrote the following report of the state of her health (the nurse telling her how to spell some of the words): "October 29th" (a mistake for Nov. 29th): "There is not much the matter with me when I am wishing it was dinner time before I had my breakfast a hour." On the 30th she was quite free from headache and very bright, and wrote the following report: "Had a good night; feeling fine this morning." After this date there was rapid and continuous improvement. She wrote a daily report of her state of health. The following are illustrations: "December 5th. Slepth well. No headache, but I am tired of lying in bed." "December 10th. Slepth well. No headache. I feel much stronger being up." On Dec. 15th she left the hospital. There had been no headache since Nov. 30th. At the time of her discharge her mental faculties were quite bright; her answers to questions were sharp and brisk, and she showed a good deal of mental quickness and intelligence. She could read and write as well as she had ever been able to do. The instantaneous rapidity with which she read such words as "dog," "Edinburgh," "How old are you?" "You are a good girl to-day," written on the blackboard before the students, was very remarkable when compared with her total inability to read any letters or words on the blackboard before the students three weeks previously. The fields of vision were quite normal (see Fig. 1, Chart 5); and the slight optic neuritis which was present at the time of her admission had completely cleared up. The temperature was normal. From the date of her admission until Nov. 21st the temperature had been subnormal (it averaged about 97° F.); after this it remained about normal, though slightly below it. The morning pulse at the date of her discharge averaged 58 and the evening pulse 64 per minute; this was at least ten beats per minute higher than at the time of her admission. The respirations throughout the course of the case were normal. The urine during the whole of the time that she was in hospital was perfectly normal. (The alterations in the fields of vision are shown in Fig. 1.)

Remarks.—I have now detailed the more important points connected with this case. As I have already said, it presents many features of great practical importance and scientific interest. The more important facts are that the patient at the time of her admission complained of severe headache, worse at night, mental stupidity and loss of memory (she stated that she felt as if she was in a mist), and dimness of vision, and that on examination slight optic neuritis, right-sided homonymous hemianopsia (with considerable constriction of the peripheral portions of the seeing halves of the fields), and a most marked defect in certain of the speech faculties were found to be present. The auditory-speech centre was practically normal. The motor-speech centre was practically normal. She was either unable to name many of the objects which were shown to her or gave them wrong names. When, however, an object was shown to her and a wrong name was given to it she would not accept it, but in almost all instances immediately recognised and accepted the right name of the object when it was stated to her. There was almost complete word-blindness. There was complete agraphia. She could neither write spontaneously nor to dictation any letter or word, and she could not copy any letter with the right hand. In addition there was marked inability to perform coördinate muscular movements with the right hand when the eyes were closed. She was unable, for example, to touch the tip of the nose with the right hand when the eyes were closed, but she could do so perfectly with the left hand. There was no defect of tactile sensibility, but there was some inability to distinguish the difference between weights. Almost immediately after the iodide of potassium was prescribed the headache was relieved, the mental condition cleared up, the word-blindness and agraphia disappeared, and the fields of vision gradually enlarged until at the date of her discharge they were perfectly normal. It is very interesting to note the order of recovery of the speech defects. She first regained the power of naming objects; she next regained the power of reading letters and words; but at this stage she was completely unable to write anything spontaneously, to copy letters, or to write to dictation. She was next able to read more words, and in the course of a few days to write a few individual letters. (It should be particularly noted that at a time when she was unable to write the letter "a" she appeared to have the mental picture of the letter correctly in her mind. She said that the letter "a" was an "o" with a crook.) Finally she completely regained the power of writing, and at the date of her discharge was able to write as well as she had ever been able to do. (As I have previously stated, she had never been to school and her writing is naturally very imperfect.)

The case is an illustration of almost complete word-blindness and of complete agraphia, the result apparently of a lesion involving the visual-speech centre and the connecting fibres which pass from the visual-speech centre to the motor-writing centre. It is probable, I think, that the lesion involved the connecting fibres which pass from the visual-speech centre to the motor-writing centre (at or about their point of emergence from the visual-speech centre) more markedly than the visual-speech centre itself; for the agraphia was more complete than the word-blindness, and when the word-blindness was recovered from—that is to say, at a time when the patient had regained the power of reading letters and words—she was still unable to write them. If I am correct in locating the lesion in the visual-word centre and the connecting fibres passing off from the visual-word centre to the writing centre, the case is a striking confirmation of the view which is now very generally held, that the action of the motor-writing centre is for the most part—Déjerine and Mirallié say entirely—regulated and governed by—in other words, under the direct control of—the associated sensory centre—i.e., the visual-speech centre. There can, I think, be little doubt as to the position of the lesion, and there certainly can be no doubt as to its pathological nature. The lesion was evidently a gumma. The history of the case (the stillbirth and miscarriages), the character of the symptoms (the headache, worse at night, and the slight optic neuritis), the superficial position of the lesion (if the localisation which I have suggested is correct), and the rapid disappearance of all the symptoms under large doses of iodide of potassium, conclusively proved the specific nature of the lesion. I see no reason for supposing that in this case a double lesion, involving the visual-speech centre and the motor-writing centre, was present. And if we grant that there was only one lesion, we must, I think, locate that lesion in the immediate neighbourhood of the visual-speech centre which is situated in the position of the left angular gyrus (and perhaps the left supra-marginal convolution). The combination of (1) word-blindness, (2) agraphia, and (3) hemianopsia (if we grant that there was only one lesion) showed that the lesion was situated in the region of the visual-speech centre, and not in the position of the motor-writing centre, which is by some authorities placed at the posterior end of the second left frontal convolution.[2] The lesion obviously did not entirely annul the function of the visual-speech centre, for the patient's mental image (memory) of letters and words was not altogether destroyed; but it is clear that the communication between the visual-speech centre and the writing centre was for the time totally interrupted. She was not only unable to write spontaneously, but she was unable to copy letters which were placed before her. When the agraphia was at its height this defect was much more marked in the right than in the left hand. Further, she was unable to write a single letter or word to dictation; and yet at this time she was able to understand everything that was said to her, to repeat anything which she was told to repeat, and to spontaneously make use of her motor-speech centre. In other words, while the auditory-speech centre,

[2] The existence of a separate writing-speech centre is a disputed point. Many authorities (such as the late Professor Charcot, Charlton Bastian, &c.) hold that such a centre exists and that lesions of that centre will produce agraphia without any other speech defects. Déjerine denies the existence of a separate writing-speech centre as distinct from the ordinary motor centres for the movements of the hand, &c., and in support of this view quotes the fact that no case has yet been recorded of pure agraphia without other speech defects, and no undoubted case has been placed on record in which a lesion of the second left frontal convolution (the supposed writing-speech centre) has produced agraphia alone.

Hosted by Google

the motor-speech centre, and the connecting fibres between these two centres appeared to be intact she was unable to write to dictation, or, to put it another way, the communicating (commissural) fibres between the auditory-speech centre and the writing centre, which in persons who are accustomed to write little,[3] as was the case in this patient, seem to pass through the visual-speech centre in order to reach the associated motor (writing) centre, were interrupted. As I have already more than once stated, there was absolutely no difficulty in articulation and speaking. When the mental stupidity which was present at the commencement of the case passed off there was absolutely no difficulty in immediately understanding everything which was said to her. Her answers to spoken questions were sharply and quickly given. My reason for locating the lesion in the neighbourhood of the angular gyrus is the combination of word-blindness and agraphia with right-sided homonymous hemianopsia.

Right-sided homonymous hemianopsia may, of course, be due to a lesion in a variety of situations (left optic tract, radiating fibres of Gratiolet, half vision centre in the back part of the occipital lobe). A lesion of the optic tract which produces hemianopsia does not produce word-blindness or agraphia. A lesion in the half-vision centre in the back part of the occipital lobe produces hemianopsia, but does not produce word-blindness or agraphia. Amongst the cases which have been reported in support of this proposition there is none more striking and conclusive than one which I have already published.[4] The case was one of embolism of the posterior cerebral artery occurring in the course of mitral stenosis. The patient was a female aged forty-seven years. The onset of the cerebral attack was attended with sudden loss of consciousness, followed for a fortnight by a condition of mental stupor and apparent inability to realise the nature of her surroundings, and resulting in permanent right-sided homonymous hemianopsia. The diagnosis, made a fortnight after the onset of the attack (when the patient's mental condition allowed of complete and satisfactory examination, the mental stupor having passed off), was embolism of the left posterior cerebral artery and softening of the half-vision centre (left cuneus) in the tip of the left occipital lobe. There was no word-blindness and no agraphia; in short, no aphasia of any kind or form. The patient lived for two years, and then died from a second apoplectic seizure. On post-mortem examination the diagnosis originally made was fully confirmed. There was a localised softening of the left cuneus and tip of the left occipital lobe and secondary descending degeneration sharply confined to the optic radiations of Gratiolet on the left side. (Plates showing photographs of the brain and the hemianopsia are published with the clinical and post-mortem record.)[5]

The combination of word-blindness with hemianopsia points to a lesion above (i.e., on the higher—the cerebral rather than the ocular side, so to speak, of) the half-vision centre—to a lesion involving either (*a*) the fibres passing from *both* half-vision centres in the tips of the occipital lobes to the left angular gyrus (visual-speech centre), or (*b*) the left angular gyrus visual-speech centre) itself. In those cases in which the lesion involves the angular gyrus itself and in which there is hemianopsia the hemianopsia is due to implication of the radiating fibres of Gratiolet, which pass immediately subjacent to the angular gyrus in their course to the half-vision centre in the back part of the occipital lobe. This case, therefore, seems to support the generally accepted view that there is a higher visual centre above, so to speak, the half-vision centre, which is concerned with visual speech.

It will be observed that in this case, in addition to the right-sided hemianopsia, there was considerable constriction of the unaffected (left) halves of the fields of vision. Several years ago I suggested that lesions in the neighbourhood of the angular gyrus—i.e., lesions above the half-vision centre in the occipital lobe—are probably attended with such peripheral constriction, while lesions which involve the half-vision centre itself do not produce such peripheral constriction. This case seems to support this supposition. The question is, however, one of much difficulty and complexity. I have met with cases which seem to disprove it. See, for example, a case of sensory "Jacksonian" epilepsy, in which a discharging lesion of the half-vision centre in the occipital lobe (verified by post-mortem examination) produced flashes of light followed by hemianopsia.[6] But it must be remembered that word-blindness does not necessarily, in fact does not usually, entail agraphia. Cases are not very uncommon in which a patient who is able to write fluently is yet absolutely unable to read a single word which he has written. It is extremely difficult to explain these differences (e.g., the facts that (*a*) in some cases of word-blindness the patient is able to write fluently and well and yet unable to read what he has written; and (*b*) that in other cases of word-blindness there is complete agraphia) if it be granted (but, so far as I know, this has not yet been proved by post-mortem examination) that in both cases—i.e., (1) cases of word-blindness without agraphia, and (2) cases of word-blindness with agraphia—the lesion may be situated in the angular gyrus. An explanation which at one time suggested itself to me is that the writing centre in the left hemisphere of the brain (second right frontal convolution) is governed by (under the action of) the higher visual centre (situated in the region of the angular gyrus) in each hemisphere; but that the visual perception of written speech characters is located in one, the left, visual centre alone (the region of the left angular gyrus). But this theory is not a satisfactory one. It may, and probably does, afford one explanation of the fact that many word-blind patients who are unable to write spontaneously (from within) can mechanically copy letters and words; but it does not explain the fact that many patients who are word-blind (who are unable to read) can write fluently, for in such cases the visual memories of letters and words must be retained (unless the patient can write by the memories of the kinæsthetic impressions which are generated in the act of writing); and if the visual memories of letters and words (of written speech) were retained in either visual speech centre, and that centre wer still in active functional connexion with either half vision centre, the patient would be able to read.

Another view, which until recently was generally accepted and which is still thought by many authorities to be the correct one, in some cases at all events, supposes that in those cases of word-blindness in which there is no agraphia the motor act of writing has become so habitual, so automatic as it were, that the patient is able to write without the supervision of the visual speech centre, by means, perhaps, of the memories (revival) of the kinæsthetic impressions connected with the act of writing. While in those cases of word-blindness in which there is agraphia the supervision and stimulation, so to speak, of the motor-writing centre by the visual-speech centre is essential, without this supervision the act of writing in such cases cannot be performed. This theory would receive striking confirmation if it could be shown, firstly (as was notably the case in our patient), that in all cases of word-blindness in which there is agraphia the patient has been accustomed to write very little (i.e., is in the position of a child who is just learning to write and in whom the discharge of the motor-writing centre has to be constantly directed by the aid of vision—that is, of the visual-word centre); and, secondly, that in all cases of word-blindness without agraphia the patients have been in the habit of writing much and with facility.

Another theory is that in cases of word-blindness with agraphia the lesion is situated in the visual-speech centre, the left angular gyrus, and perhaps the left supra-marginal convolution; whereas in cases of word-blindness without agraphia the lesion does not involve the visual-speech centre itself, but involves the connecting fibres which pass to the visual-speech centre from *both* half-vision centres in the back part of the occipital lobes. This theory is supported by three cases which have been recorded by Déjerine, Redlich, and Wyllie, and seems to be accepted by Dr. Wyllie as conclusively proved. Dr. Wyllie says: "It has recently been shown quite conclusively that the visual images at C [visual-speech centre] are in all cases important, not only for the reception and interpretation of written and printed

[3] In some cases of word-blindness in which the patient is unable to write spontaneously (i.e., from within as the result of stimulation from the visual-speech centre) the power of writing to dictation is preserved. In such cases it is reasonable to suppose that there is a direct connexion between the auditory-speech centre and the motor-writing centre. In persons who are accustomed to write much, and especially in persons who are accustomed to write much to dictation, it is probable that the motor writing-speech centre may be thrown into action either by the visual-speech centre or by the auditory-speech centre.

Hosted by Google

speech, but also for the production of writing. It has been shown, in fact, that when the centre C [visual-speech centre] is destroyed the patient can neither read nor write. As to reading, he is word-blind; as to writing, he has amnesia literarum, and therefore cannot call up in his mind the visual images of letters and words required for purposes of writing. It is now considered to be improbable that the graphic-motor images at D [motor-writing centre] can in any single case be so strongly imprinted as to suffice for the act of writing independently of any guidance from the visual images at C [visual-speech centre]. How, then, are the cases of pure word-blindness without agraphia—in which the patient can write correctly, though he cannot read even that which he himself has written—to be accounted for? It is now believed that in these cases the visual-word centre C remains intact, and that so also do the pathways for the influences by which it is acted upon *from within* when words revived in the mind are being translated into writing; but that, on the other hand, the pathways along which, as we shall see presently, influences pass from the primary visual centres, in the two occipital lobes, to the visual-word centre C, in the angular and supra-marginal convolutions, are cut across, so that the word images in C, though they can still be revived *from within*, can no longer be reached and revived by impressions coming to them *from without*. Destruction of the visual-word centre C, therefore, causes both word-blindness and agraphia; but the cutting off of the visual-word centre C from the primary visual centres in the two occipital lobes causes simple word-blindness without agraphia."[7] The arguments which Déjerine and Mirallié advance against the existence of a separate writing-speech centre, lesions of which will cause pure agraphia, are undoubtedly very strong. Future observations will, no doubt, decide the point definitely one way or the other, and determine whether the memories of the muscular movements (kinæsthetic impressions generated during the production of the movements concerned in the act of writing) may not in some cases be alone sufficient to enable a patient who has been accustomed to write much to write at all events in some degree. But I will leave the discussion of this difficult and debateable point until I come to consider the subject of aphasia as a whole.

The point, then, of most importance which this case seems to illustrate is that a lesion involving the conducting fibres which pass from the visual-speech centre to the motor-writing centre, in a person who has been accustomed to write little, produces a condition of complete agraphia (inability to write spontaneously, to copy, or to write from dictation). In other words, this case seems to suggest that a lesion which completely interrupts the connecting fibres which pass from the visual-speech centre to the motor-writing centre (whether that centre is a separate writing-speech centre, as Charcot and Bastian suppose, or merely the ordinary motor centre for the movements of the right hand, as Déjerine thinks) will produce agraphia, leaving internal visual speech unaffected. If this is so, and if Déjerine's views are correct, we may therefore say that:—1. A lesion which interrupts the conducting fibres which pass from both half-vision centres to the visual-speech centre (left angular gyrus) will produce complete word-blindness, but no agraphia. In these cases the patient is unable to read printed or written characters; he can write spontaneously, but he is unable to read what he writes. 2. A lesion which completely destroys the visual-speech centre itself (left angular gyrus) will produce complete word-blindness and complete agraphia (unless, as Charcot and Charlton Bastian, &c., suppose, the kinæsthetic memories are alone sufficient to enable the patient to write; but this, as we have seen, is very doubtful). 3. A lesion which completely interrupts the fibres which pass from the visual-speech centre (angular gyrus) to the motor-writing centre will produce pure agraphia—agraphia without word-blindness. If such a lesion occurs, it must be very rare. Further (4), if a separate writing-*speech* centre exists (but, as I have already stated, its existence is stoutly denied by Déjerine) complete destruction of this centre and of this centre alone will produce pure agraphia—agraphia without word-blindness. Complete destruction of the visual-speech centre usually entails, as Déjerine and Mirallié have shown, other speech defects (in auditory and vocal speech); but I need not refer to them at present. I merely refer to the defects in visual speech and in writing.

It will be noted that in this case there was no disturbance of tactile sensibility, but there was distinct loss of the muscular sense and power of coördinating the movements in the right upper extremity when the eyes were closed, and yet there was absolutely no paralysis and the grasping power of the two hands was unimpaired. The patient had lost the mental idea of some of the movements of the right hand; when the eyes were open she could coördinate her movements correctly, but when the eyes were closed she was unable to touch the tip of the nose with the left fore-finger. It is difficult, perhaps, to give an explanation of these facts (granting that the lesion was confined to the position of the angular gyrus), unless it be supposed that the cortical grey matter in the neighbourhood of the higher centre for vision exercises an important influence upon the co-ordination of muscular movements of the right hand, not only in those movements concerned in the act of writing, but other movements, such as touching the tip of the nose. And in this connexion it is important to note that Nothnagel and others have suggested from the observation of clinical cases that "the parietal lobe in its inferior part contains a centre for the registration of motor residua (as Dr. E. C. Seguin terms the ingoing or kinæsthetic impressions which attend and result from muscular movements), and that the centres in the motor zone are really motor centres."[8] And here let me state that some word-blind patients are able to read by tracing the letters and words (which they cannot decipher, so to speak, by the sense of sight) with the fore-finger either on paper or in the air—in other words, by the revival in consciousness of the kinæsthetic impressions attending the act of writing. Déjerine and Mirallié state that this is only possible in cases of subcortical or pure word-blindness. This fact seems to me to suggest that the cortical centre in which the kinæsthetic impressions connected with the act of writing are stored is the angular gyrus or adjacent part of the supra-marginal convolution. And in support of this supposition, which, so far as I know, has not been advanced before, is the fact that in this case of word-blindness and agraphia, the result apparently of a lesion in the visual-speech centre and its immediate neighbourhood, there was definite incoördination of the movements of the right hand. According to this view, both the visual and kinæsthetic impressions concerned in the act of writing are stored up in the same or closely adjacent cortical centres. If future observations should show that this supposition is correct many of our present difficulties with regard to agraphia would be easily explained.

It is impossible, of course, to believe that in this case, in which such rapid improvement occurred under anti-syphilitic treatment, there was any "destroying" lesion. The only explanation of the rapid recovery from the complete condition of agraphia and almost complete visual word-blindness which were present is, I think, that there was a specific lesion on the surface of the brain in the region of the left angular gyrus which temporarily arrested or inhibited (either by pressure or by interfering with the blood-supply, or in both ways) the function of the angular gyrus, and more especially of the connecting fibres passing from it (the visual-speech centre) to the motor-writing centre. Further, the case is certainly one of the most remarkable illustrations which has come under my own personal observation of the extraordinary effect which large doses of iodide of potassium have on gummatous lesions.

The case shows the great importance of testing the fields of vision and the patient's power of reading and writing in all obscure cases of cerebral disease.[9] I have met with other cases which also strongly support the same proposition. I will take an early opportunity of detailing some of them and of discussing the whole subject of aphasia more fully.

(To be continued.)

[7] The Disorders of Speech, by Dr. John Wyllie, p. 333.

[8] See Abstract on Cerebral and Spinal Localisation, by Dr. E. C. Seguin, in Sajous' Annual of the Universal Medical Sciences, 1888, vol. i., p. 4.

[9] In some cases the mental condition of the patient unfortunately renders it impossible to get a perimeter chart or even to ascertain the condition of the fields of vision by the rough test.

HEALTH OF HORFIELD.—At the meeting of the Horfield Urban District Council, Horfield, Bristol, held on Feb. 23rd, Mr. J. H. Parry, L.R.C.P. and S. Edin., the medical officer of health, presented his annual report, which stated that 328 births had been registered during 1896, being at the rate of 28·5 per 1000. The deaths numbered 129, or at the rate of 11·2 per 1000; of these 35 were in infants under one year, and included 10 from premature birth.

ON THE RADICAL CURE OF HYDROCELE BY EXCISION OF THE SAC, WITH NOTES OF TWENTY-TWO CASES.

BY F. A. SOUTHAM, M.B. OXON., F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY; LECTURER ON OPERATIVE SURGERY, OWENS COLLEGE.

IN previous numbers of THE LANCET[1] I have recorded several instances of radical cure of hydrocele by excision of the sac, and called attention to the good results attending this mode of treatment, which I have now adopted in twenty-two cases, brief particulars of which will be found in the table given below. A consideration of these cases may perhaps be of interest, as they serve to illustrate the chief conditions which call for the performance of this operation.

TABLE OF CASES OF RADICAL CURE OF HYDROCELE BY EXCISION OF THE SAC.

No.	Age.	Date of operation.	Nature of hydrocele.	Previous treatment.	Remarks.
1.	47	June, 1886.	Vaginal.	Tapped four times.	—
2.	40	April, 1887.	,,	Tapped seven times; injected once with carbolic acid.	The sac wall was very thick.
3.	53	May, 1887.	,,	Tapped three times.	—
4.	38	July, 1887.	,,	Tapped three times.	—
5.	58	January, 1888.	,,	Tapped eight or nine times.	Suppuration in the tunica vaginalis after last tapping; sac wall thick and inflamed.
6.	44	July, 1888.	,,	Tapped several times; injected once with iodine.	Testis adherent to the anterior wall of the tunica vaginalis.
7.	55	February, 1889.	,,	Tapped three times.	Sac wall cartilaginous, from a quarter to half an inch in thickness.
8.	43	February, 1891.	,,	Tapped twice.	Multilocular hydrocele.
9.	25	March, 1891.	Encysted.	None.	Present for many years; size of orange; thick sac wall.
10.	62	April, 1891.	Vaginal.	Tapped twice quite recently.	Twenty years' duration; sac wall calcified; scrotum gangrenous; pus in the tunica vaginalis; radical cure of inguinal hernia on same side also performed.
11.	23	May, 1891.	,,	Tapped twice; injected once with iodine.	Hæmorrhage into the tunica vaginalis after last tapping; thick sac wall.
12.	31	December, 1891.	Encysted.	None.	Size of orange; radical cure of inguinal hernia on the same side also performed.
13.	45	May, 1894.	Vaginal.	Tapped three times.	—
14.	51	October, 1894.	,,	Tapped twice quite recently.	Bloody fluid drawn off at the second tapping, followed by suppuration in the sac and sloughing of the sac wall.
15.	31	February, 1895.	,,	None.	Present for several years; recently contracted gonorrhœa, followed by acute epididymitis and suppuration in the tunica vaginalis; the sac wall was thick and inflamed.
16.	54	February, 1895.	,,	Tapped twice recently.	Many years' duration; blood drawn off at the second tapping; re-filled rapidly. The tunica vaginalis contained blood-clot and fluid; the sac wall was very thick.
17.	18	August, 1895.	,,	Tapped several times; injected once with perchloride of mercury.	The sac wall was thickened.
18.	18	March, 1896.	Encysted.	None.	—
19.	22	June, 1896.	Vaginal.	,,	Bilocular hydrocele; radical cure of inguinal hernia on the opposite side also performed.
20.	7	July, 1896.	Encysted.	Tapped twice.	Present since infancy; size of small orange; thick sac wall.
21.	62	August, 1896.	Vaginal.	None.	Several years' duration.
22.	33	September, 1896.	,,	,,	Present since boyhood.

Briefly described, the operation is carried out in the following way. The cavity of the tunica vaginalis is laid open by a vertical incision, from two to three inches in length, made from the front through the tissues of the scrotum. The fluid contents of the hydrocele having escaped, the tunica vaginalis is dissected out on either side up to the point where it is reflected on the testis and lower part of the cord. The whole of the parietal layer is then removed by cutting through it close to its reflection upon the cord and testis with a pair of scissors. All bleeding having been arrested, the wound is then closed, no drainage having been employed in my recent cases, and if pressure is maintained by pads of wood-wool so as to keep the deep parts of the wound in apposition, and the scrotum is afterwards kept well elevated, healing quickly takes place, and at the end of ten days or a fortnight the patient is usually able to get about wearing a suspensory bandage. Though some thickening remains at the seat of operation for a time it gradually subsides, and in the course of a few months the scar will have almost disappeared, the scrotal tissues moving so freely over the surface of the testis that it is often difficult to detect that any operation has been performed. In cases of encysted hydrocele the operation differs only in the fact that the entire sac is removed. The chief conditions which call for the performance of this operation are as follows:—1. When a patient is anxious for a radical cure, but does not wish to run the risk of an unsuccessful attempt by injection. It was for this reason that excision of the sac was performed in many of the cases. 2. Old hydroceles, where the sac wall is thickened and rigid, and consequently incapable of completely collapsing after the fluid is drawn off by tapping. It is under these conditions that the treatment by injection is liable to fail. Considerable thickening of the sac wall was present in many of the cases, while in Cases 2 and 7 this condition was very marked, the tunica vaginalis being in places more than a quarter of an inch in thickness and of cartilaginous consistence. In Case 10, where the hydrocele had existed for a period of twenty years, the sac wall was in addition distinctly calcified. 3. When injection has been tried and failed. In Case 2 the hydrocele had been previously injected with carbolic acid; in Cases 6 and 11 iodine had been used, and in Case 17 perchloride of mercury, but in each instance without success. 4. When suppuration has taken place in the sac of a hydrocele after its contents have been removed by tapping. This complication, which is liable to occur after evacuation of the fluid in old hydroceles, was present in Cases 5, 10, and 14, and in each the tunica vaginalis was in an inflamed and unhealthy condition. In one instance, Case 10, the scrotal tissues over the front of the swelling were distinctly gangrenous. In Case 14 the sac was at first incised and drained, but as the discharge, which was mixed with broken-down blood clot, showed no signs of abatement

[1] THE LANCET, Sept. 10th, 1887; Oct. 26th, 1889; and July 25th, 1891.

Hosted by Google

the tunica vaginalis was afterwards excised and the wound closed, with the result that healing took place without any further suppuration. In Case 15 suppuration had occurred in the sac of an old hydrocele as the result of an attack of gonorrhœal epididymitis. 5. When a hæmatocele follows the operation of tapping a hydrocele. This complication was present in two instances, Cases 11 and 16, the thickened condition of the sac wall, which was incapable of collapsing, doubtless accounting for the occurrence of the bleeding. 6. When a hydrocele is associated with an inguinal hernia upon which it is desirable to perform a radical cure. Both these conditions were present in Cases 10, 12, and 19. 7. Two rare conditions in which the operation proved extremely useful were those found in Cases 6 and 8—viz., (*a*) an adherent condition of the testis to the anterior wall of the scrotum, where it formed a distinct prominence, the result of previous tappings and an unsuccessful injection with iodine; and (*b*) a multilocular hydrocele, the cavity of the tunica vaginalis being divided by numerous septa into distinct compartments, a condition which could not be satisfactorily treated by any other measure than by excision of the sac. 8. In cases of encysted hydrocele the entire sac can be excised, and the whole of the secreting surface is therefore removed, as in Cases 9, 12, 18, and 20. A reference to the table will show that advanced age is no bar to the operation, five of the patients being over fifty and two over sixty years of age. As regards the result of the operation, I have not met with a single case where there has been a recurrence of the hydrocele; and provided it is carried out in the way described, care being taken to remove the whole of the parietal layer of the tunica vaginalis, I am of opinion that excision of the sac is the only certain method of radical cure.

Manchester.

FOREIGN BODY IN THE LENS FOR SIXTEEN YEARS, THE LENS REMAINING CLEAR.

BY T. BRITTIN ARCHER, M.R.C.S. ENG.,
SENIOR SURGEON, CENTRAL LONDON OPHTHALMIC HOSPITAL.

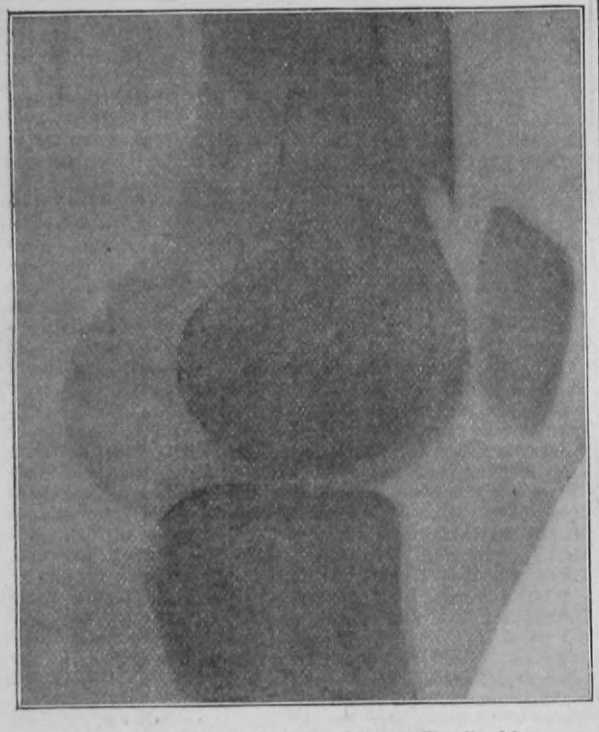
A MAN, aged thirty years, married, of healthy appearance, with good family history, and an intelligent person, came to the Central London Ophthalmic Hospital on Sept. 17th, 1896, complaining that when he was reading a paper four days previously he noticed that there appeared to be a cloud over the left eye, which somewhat obscured the print whilst reading, and the cloud had remained up to the date of coming to the hospital. Nothing peculiar was observable about the eyes by daylight. Tension was normal in both, the pupil reflexes were all present, both eyes were quiet, and there was no inflammation. He had had no blow on the eye or accident of any sort. Right vision = $\frac{6}{6}$ without glass, Jaeger No. 1 up to 14 centimetres; left + 1·75 = $\frac{6}{18}$, Jaeger No. 8 at 25 centimetres indistinctly without glass. He was positive he could see quite well with the left eye up to four days before. On examination in the dark room, the left lens was found to be cataractous, with many well-marked striæ, stellate, partially obscuring the fundus; at the posterior part of the lens was seen, indistinctly by reason of the striæ, what appeared to be a fine piece of glittering wire, with a small spot of opaque posterior capsule immediately behind, and forming a white background to the assumed foreign body. The object was, allowing for it being seen under a high lens, about three millimetres long and half a millimetre broad, lying nearly vertically as regards its length in the lens, inclined slightly towards the temporal side, and having the lower extremity slightly curved forwards. On the anterior surface of the iris (a blue-grey one), in the lower and nasal quarter segment of the iris circle, was a fine blue-black line about a millimetre long running parallel with the pupillary border of the iris, and half-way between that border and the ciliary border, but rather nearer the pupillary border. There was no opacity in the cornea. The right fundus was normal. The patient could not at first recollect any accident to the eye, but on pressure he suddenly remembered that sixteen years previously, when he was fourteen years of age, he filled a bit of old gas-pipe with gunpowder and it prematurely exploded by accident. This occurred to the right side of the face, on which are two powder marks, but he declared that neither of his eyes was in any way affected by the explosion. As it was doubtful at this first visit what the object was, atropine drops were ordered and he was told to come again in four days. On the 21st the left lens had become more opaque. Vision = $\frac{6}{9}$. The foreign body could not be seen so distinctly; the fundus was quite obscured. The specific gravity of the urine was 1024; it was acid, and there was no albumin or sugar. The eye was quiet. The patient was admitted to the hospital with a view to the extraction of the lens and the foreign body. On the 24th, on examining the lens, the opacity had entirely cleared up, save very small and short striæ at the periphery; the foreign body stood out clearly to the view in the lens; the fundus was easily seen and was normal; and the vision with + 1·75 was $\frac{6}{12}$ two letters. In face of this extraordinary condition the operation was postponed. On Oct. 1st the vision = $\frac{6}{9}$; the opacity of the lens returned and increased. The foreign body seemed to have shifted slightly with regard to the opaque spot in the capsule behind it. The eye was quiet and the lens seemed to be rapidly softening. On the 5th the lens (left) was removed by a semilunar incision at the sclero-corneal junction with an iridectomy. The lens was very fluid, slightly milky in colour, and easily delivered; one small drop of vitreous presented, which was incised. This was probably due to the posterior capsule being lacerated by the foreign body or from degenerative changes set up from the original impact; it tore on delivery of the lens. On examination of the débris of the lens, which had lost all its form, no foreign body was discovered, but on raising the upper lid it was found resting on the ocular conjunctiva just above the section, having been delivered with the lens. On the 6th the eye was quiet and remained so until the 15th, when the patient was discharged, the eye having made a rapid recovery from the operation. Vision + 10 D. = $\frac{6}{9}$. There was some small amount of soft lens matter remaining, but not sufficient to obscure the fundus. On the 29th the eye was quiet. Vision + 10 = $\frac{6}{12}$. On Nov. 23rd vision + 10 = $\frac{6}{9}$. There was a fine thread of capsule intersecting the pupil.

Dr. Norman Maclehose, pathologist to the hospital, reports on the foreign body: "There is no possible doubt as to the fragment being iron or steel; it is heavy, sinks rapidly in water, slowly in glycerine, is strongly attracted by the magnet. There are one or two fine filaments of wool or cotton adhering to it, but no evidence of incrustation with new cells or organic matter. The foreign body measures 2½ mm. long and ¼ mm. broad."

Remarks.—There seem to be many points of interest with regard to this case. First, as to how the foreign body got into the lens. It is assumed that the fragment was shot into the man's eye when he was aged fourteen years by the explosion of the loaded gas-pipe, and it seems difficult to refuse this explanation of its presence, backed up by the local evidence. This is the solitary accident in the man's life. There are powder marks on the right cheek and presumably a charred powder stain on the iris of the left eye, in a line with the direction the foreign body would take in travelling from right to left. That there is no corneal opacity is not important, as the original wound would be very small, and time (sixteen years) could well obliterate it. That the stain on the iris is not physiological may safely be accepted as its plane runs at right angles to the course it ought to pursue were it so, and also from its peculiar coal blackness. Presuming that the foreign body passed from right to left, pierced the cornea at its sclero-corneal junction, passed through the iris, and lodged in the posterior part of the left lens, and taking into account the position in which it lay, then there is local evidence all along the line of this theory of its presence. Secondly, it set up no irritation at the time. The size may account for it not setting up any change in the lens at first, and one can best realise what that size was by describing it, when viewed by the naked eye on a bit of white notepaper, as like half of a small eyelash. Its real measurement has been given. Thirdly, that for sixteen years the lens remained clear. Of course the man's statement has here to be believed, but he ought to be a good judge on this point, he being a carpenter, an occupation in which at times of taking measurements (antero-posterior) binocular vision is almost a necessity, and he would soon have found it out if one eye was failing. His statement of its discovery is very clear, and luckily when the lens changes did come they were watched by three skilled ophthalmoscopists and seen

Hosted by Google

to be very rapid. Doubtless there were always the slight opacity in the posterior capsule and the opacity of the foreign body itself, but these were not sufficient to interfere with good vision. What did start the secondary softening is doubtful; probably some jar or contusion experienced in following out his trade of which he took no notice. Lastly, that the lens during its softening cleared temporarily after having become opaque is difficult to explain. That it did occur is beyond dispute, as the condition was corroborated by three observers, and though perhaps one could easily put forward several theories to account for it, still they would lack the evidence of absolute certainty.



The lens on its delivery was placed inadvertently on a towel that covered the cushion on which the patient's head rested and, being entirely fluid, soaked immediately away. This is to be regretted, as no examination of it was made.

Nottingham-place, W.

NOTE ON A SKIAGRAPH OF A CASE OF FRACTURED FEMUR.

BY SURGEON-COLONEL W. F. STEVENSON,
PROFESSOR OF SURGERY,
AND
SURGEON-MAJOR WHITEHEAD,
LATE ASSISTANT PROFESSOR OF SURGERY, ARMY MEDICAL SCHOOL, NETLEY.

THIS skiagraph has, we consider, certain points of interest about it. At first sight it appears to be a picture of a recent fracture of the lower end of the femur in which a considerable amount of deformity and over-riding of the lower end of the upper fragment exists, whereas it really represents the present condition of the bones in a case of fracture close above the knee-joint which

Skiagraph of knee-joint and portion of femur. The site of fracture is clearly shown and the lower end of the upper fragment appears very sharp. For explanation of this see text.

occurred six months ago. The points worthy of attention connected with it are—(1) the end of the upper fragment appears jagged and sharply defined, as one might expect to see in a recent case—quite as much so as was depicted in a skiagraph of the same case taken by Mr. Sydney Rowland a few days after the accident happened; no attempt has apparently been made by nature to round off the end of the bone; (2) on examination of the limb no projection of the bone can be felt at the site of fracture; the union appears to be smooth and even; (3) the shortening amounts to barely half an inch; (4) the man walks without any sign of lameness; and (5) he feels no pain in the part. From the surgical point of view, the result is as good as could be expected under the circumstances of a fracture in the position indicated. That the bone is in fact as sharp as it appears in the skiagraph we do not believe; what probably has occurred is that the x rays have traversed the more recent callous material, which really does round off the end, without throwing a shadow on the plate, while the older bone is clearly defined.

Mr. Edmund Owen[1] suggests a misuse to which skiagraphy may be put in the future when he remarks, *apropos* to a similar case of his own: "What may a British jury think when a skiagraph of some case is being explained by the sharp advocate of a claimant for damages for malpraxis?" The x rays exhibited in Mr. Owen's case an apparent deformity which "really did not matter," as the result was otherwise as good as surgery could achieve, and the above would seem to be another case in point. The surgeon is, in fact, liable to find himself "given away," and imaginative patients to consider themselves badly treated, if they have their broken bones skiagraphed by Roentgen's method.

Netley.

"A QUESTION FOR ANÆSTHETISTS."

PNEUMONIA AFTER SURGICAL OPERATIONS: AN ANÆSTHETIST'S POINT OF VIEW.[2]

BY J. FREDERICK W. SILK, M.D. LOND.,
ANÆSTHETIST TO KING'S COLLEGE HOSPITAL AND TO GUY'S HOSPITAL DENTAL SCHOOL.

IN THE LANCET of Feb. 20th, 1897, under the heading "A Question for Anæsthetists," Mr. Clement Lucas states that in his experience, pneumonia after surgical operations is of too frequent occurrence to be explicable either upon the hypothesis of prior infection, or on that of simple exposure to cold; that pneumonia is as invariably the result of germ infection as is tubercle; and the question he raises, therefore, is—May not the masks and face-pieces used in the administration of the anæsthetic be a possible source of infection? Surgeons in general and anæsthetists in particular must, I am sure, feel indebted to Mr. Lucas for the candid manner in which he has brought the matter before them.

The frequency of pneumonia after operations.—As I read the paper, cases of transitory bronchial irritation are not referred to, but only those graver inflammatory conditions involving elevation of temperature and other definite signs of marked pneumonia. Is it a fact that such cases are really of frequent occurrence in modern non-septic surgery? In the days before anæsthetics and antiseptics pneumonia was a well-recognised and most frequent cause of death after surgical injury and operation, and the fact is constantly referred to by the medical writers and lecturers of the time. For instance, in the Guy's Hospital Reports for 1843 is a paper by Dr. Norman Chevers dealing with the different causes of death after operations; pneumonia is given a prominent place in the list, and some observations of Erichsen are quoted in which the latter states that of forty-one deaths after surgical injury no less than twenty-three exhibited signs of pneumonia. On the other hand, it is really remarkable how silent the statistics of modern surgery are upon the subject—in fact, it may be said that it is the legitimate boast of surgeons nowadays, founded upon well-authenticated published records, that elevation of temperature, from whatever cause, is distinctly exceptional after operations. In the St. Bartholomew's Hospital Reports for 1895 there are tabulated records of 1774 operations; in those of St. Thomas's Hospital for 1894 there are 1376; in those of King's College Hospital, vol. ii., 1895–96, there are 915; and in those of Middlesex Hospital, 1894, there are 912. Out of this total of nearly 5000 I have with some difficulty found references

[1] THE LANCET, Aug. 29th, 1896.

[2] A paper read before the Society of Anæsthetists on March 18th, 1897.

Hosted by Google

to about thirteen cases of pneumonia; of these, no less than eight were jaw or tongue cases, two were in rectal operations, in one a foreign body was subsequently found in the bronchus, and one was a case in which cough and a slight rise in temperature were, apparently, the only signs of pneumonia. Practically, therefore, we have but one case in 5000 which is at all parallel to the case cited by Mr. Lucas as typical. Further, Prescott, in discussing this very subject in the *Boston Medical and Surgical Journal* for 1895, comes to the conclusion that in an estimated 40,000 cases of etherisation there were only three cases of acute lobar pneumonia. Judging from these sources of information, therefore, Mr. Lucas's experience seems to be very exceptional, and one is almost inclined to commiserate him; but possibly, now that attention has been directed to the matter, the records of future years will show a few more cases, so that after all there may be some justification for the view that cases of pneumonia (as distinguished from bronchial irritation) occur with undesirable frequency. At present, however, the belief in the occurrence of pneumonia after surgical operations appears to be a traditional survival of the pre-anæsthetic and pre-antiseptic days.

The bacillary origin of pneumonia.—If simple bronchial troubles as well as those of a pronounced pneumonic type are included, it must first be shown that there is a specific micro-organism which is the *causa causans* of such conditions. Whatever may be the theoretical probabilities of this, I hardly think that any bacteriologist is prepared as yet to proclaim the discovery of the bacillus of bronchitis. With regard to the bacillus of pneumonia it may be pointed out that Crookshank and Sternberg, in their respective text-books, enumerate no less than three micro-organisms which are said to produce, or are at any rate present in the sputum of, pneumonia—viz., the pneumococcus of Friedlander, an altogether different one of Sternberg, and a third of Klein; and not only so, but it seems to me that the inoculation experiments with any one of these are by no means conclusive, or even uniform. Add to this the fact that one or other of the specific forms referred to is often found in the normal buccal débris, and then I think that we can hardly come to any other conclusion than that, from the point of view of infective organisms, our knowledge of the subject is still very incomplete; it does not carry us much further than the stage of probabilities, or entitle us to say much more than that the pathological conditions and secretions of pneumonia furnish very suitable media for the growth of the organisms in question.

Masks and face pieces as a source of infection.—Assuming for the sake of argument that cases of pneumonia after operations are of tolerably frequent occurrence and that such cases are always due to infective organisms, I would submit that of all places such organisms are least likely to be found in the masks and face-pieces of the anæsthetist. Sternberg, in his "Text-book of Bacteriology," quotes some interesting experiments which tend to support this view. Prolonged exposure to nitrous oxide, though it did not absolutely destroy some organisms that were experimented upon, materially interfered with their development and restrained their growth. Anthrax spores, the most obstinate of known organisms, were not absolutely destroyed by immersion in chloroform, but the cholera bacillus, the typhoid bacillus, and the anthrax bacillus were killed in a very short time when placed in weak watery solutions of the drug (from ¼ to ½ per cent.). Ten minutes' exposure to ether destroyed tubercle bacilli. Then, again, it is very well known that absolute alcohol (a constituent of the A.C.E. mixture) is rapidly and permanently fatal to nearly all micro-organisms. I do not know of any experiments that have been made with the organisms contained in pneumonic sputum, but there is no reason to doubt that the result would be in accord with the above. It is not a little curious, too, that the least potent of the drugs referred to, both from the anæsthetist's and from the bacteriologist's point of view,—viz, nitrous oxide—is the one which is probably used more frequently than all the others put together, and under conditions which would be most likely to convey infection. Except when a foreign body has slipped into the trachea it has never, to my knowledge, been recorded, that the use of nitrous oxide has been followed by anything approaching pneumonia. On the other hand, chloroform, the most powerful of anæsthetics and a very strong antiseptic, which is used without a mask, is the anæsthetic most frequently employed in septic jaw and tongue cases, in which the mortality from pneumonia is exceptionally high

Although I cannot agree with Mr. Lucas in his deductions I should like very cordially to endorse his views as to the desirability, for several reasons, of scrupulous cleanliness whether in the matter of surgical instruments or inhalers. As he is not an anæsthetist it is of course excusable that he should have overlooked several improvements in apparatus, tending to facilitate cleaning, that have been introduced of late years. Among others I would mention the following—viz., as far back as 1887 Mr. Lloyd suggested a light, inexpensive, destroyable bag for use with the portable Clover's inhaler; Dr. Dudley Buxton has adopted an easily cleaned bag for the larger Clover's inhaler; and Mr. Davis has brought forward a metal inhaler of the Ormsby pattern. I venture to think, too, that the celluloid inhalers for the A.C.E. mixture, which I introduced some years ago, are steps in the same direction; and further, some two years or so ago I placed in the operating theatre of Guy's Hospital, and showed at a meeting of the Society of Anæsthetists, a form of metal inhaler, one of the advantages which I claimed for it being that it met the demand for an inhaler which could be subjected to the same aseptic treatment as the instruments employed in the operation.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF IMPALEMENT.

BY JOHN JOSEPH STACK, L.R.C.P. EDIN., L.R.C.S. IREL.

ONE night at the end of last February I was called by a police officer to attend a man who was literally hooked on to an iron gate opening off a street in the neighbourhood of New Cross. The spike of the iron railing had entered beneath the chin, penetrated the floor of the mouth, issued through the mouth, and was jammed against the right cheek, the point reaching as far as the internal canthus of the eye. The man was making violent but unavailing efforts to disengage himself, and must have been in that position for a long time, as he seemed to be exhausted from his prolonged struggling. My first idea was to raise his head off the railings, but this was not easy, as the shoulders of the pike-shaped rail were locked in by the narrow horizontal rami of the lower jawbone, so that the head was held fast. I then turned the head in a line with the gate, aided by several constables who lifted the body from the ground. In this position the shoulders of the end of the rail were in the long axis of the "maxillary outlet," so that the man was easily released from his distressing position and was conveyed on an ambulance to the hospital. There was only very slight hæmorrhage; he was intoxicated and unable to give any account of himself. How he got on the gate, whether by deliberately thrusting himself on the spike or whether he was placed there by others, I am unable to say. I am indebted to Mr. M. K. Tebay, house surgeon of the Miller Hospital at Greenwich, for further particulars of the case. The man is now practically well; the wound in the floor of his mouth is granulating very favourably, and he will soon leave the hospital. I ought to add that all the front teeth in the upper jaw were broken off.

New Cross-road, S.E.

NOTES ON A CASE OF WOUND OF THE PALMAR ARCH NECESSITATING LIGATURE OF THE BRACHIAL ARTERY.

BY S. J. ROSS, M.B., CH.B. VICT.

IN May, 1896, I was called to see a boy who had run a spike into the palm of his right hand. I saw him almost immediately after the accident. He had lost a considerable amount of blood, and the hæmorrhage was still very free from the wound. A pad of cyanide gauze over the palmar wound was applied. The elbow joint was flexed over a roller bandage,

Hosted by Google

and the patient was put to bed. Two days afterwards the hæmorrhage still persisted slightly, but gave no cause for alarm. On the third day, however, I was called to see the patient, as the hæmorrhage had recurred as profusely as before. He was becoming blanched, the pulse was frequent, and he was getting restless—indications for more active interference. I decided to ligature the brachial artery at the insertion of the coraco-brachialis muscle. This I did. The limb was then wrapped up in cotton-wool, and in three weeks both the palmar and brachial wounds were soundly healed.

My reason for deciding to ligature the brachial artery instead of the radial and ulnar was that the boy was practically in a state of collapse, and consequently I considered that if I ligatured the two vessels separately there would probably be a recurrence of hæmorrhage, due to the free anastomosis between the branches of these vessels; so that I thought it better to place the patient beyond even the possibility of such recurrence. I have carefully watched the subsequent history of the case, and know that the boy is in perfect health and has not been in the least inconvenienced by the operation.

GUY'S HOSPITAL.

A CASE OF PNEUMO-BACILLARY CONJUNCTIVITIS.

(Under the care of Dr. BRAILEY.)

IN the following case of conjunctivitis the pneumo-bacillus of Friedländer, which was present in the conjunctival sac, appeared to have a causal, and not merely an accidental, relationship to the lesion. For the notes of this case we are indebted to Dr. J. Eyre.

The patient, a feeble old man, aged sixty years, presented himself at the out-patient department complaining of pain, constant watering of the eyes, and failing sight, the symptoms dating from six months previously, when the eyes were very "blood-shot" and a purulent discharge was present. On examination there was found to be considerable injection of the vessels of the palpebral conjunctiva and to a less extent of the bulbar conjunctiva; a certain amount of photophobia and very obvious lacrymation were also noted—in fact, all the appearances were those of a simple chronic conjunctivitis. When, however, the caruncle was examined its surface was found to be hidden by a thick, viscid, shining, white film, which could easily be removed piecemeal, having no very intimate attachment. The actual surface of the caruncle, when exposed, appeared to be somewhat hyperæmic, but not raw or bleeding; the follicles of this body were also found to contain a similar material, which could be expressed by squeezing the caruncle between the points of a pair of forceps. The affection was bilateral. Vision in each eye = $\frac{6}{9}$, with + 0·5 D. sph. = $\frac{6}{6}$, and with + 5 D. sph. the patient read J. 1 at a distance of eleven inches. Treatment appeared to have no effect upon this case, and although the patient was under observation for about two months the conjunctivitis showed no definite improvement. The "pseudo-membrane" invariably re-formed within twenty-four hours of removal. Lotions of boric acid were useless; those of perchloride of mercury, 1 in 5000, were not followed by any obvious benefit. The film was removed from the caruncle, and the surface of this latter painted with 1 per cent., and subsequently with 2 per cent., solutions of the perchloride of mercury, with the result that the formation of the viscid layer was delayed for forty-eight hours, whilst the effect of 1, 2, and 3 per cent. solutions of nitrate of silver was equally transient.

Remarks by Dr. EYRE.—As regards the bacteriological aspect of the case the microscopical examination of the "pseudo-membrane" removed from the caruncle showed that it was simply a mass of degenerated epithelial cells, desquamated from the surface of the conjunctiva, with a few granular leucocytes. In, upon, and between the squamous cells were seen large numbers of short, oval bacilli, either single or arranged in pairs as diplo-bacilli (in this latter case the individual bacilli were often so short that the organism simulated a diplococcus), which did not retain their stain when treated by Gram's method. No capsule could be demonstrated. Cover-slip smear preparations made direct from the conjunctival secretion showed a precisely similar bacillus in enormous numbers; no other micro-organisms could be detected. Cultivations were made from the secretion contained in the conjunctival sac and also from the material removed from the surface of the caruncle, on blood serum and on agar-agar. After twenty-four hours' incubation at 37·5° C. all the tubes were found to contain a growth which consisted of a pure culture of a non-motile, pleomorphic bacillus not staining by Gram's method. Sub-cultivations on various media demonstrated the following biological characters:—1. On agar (streak) at twenty-four hours a shining, opaque white, viscid layer formed, exhibiting a pearly lustre; the growth tended to spread from the needle track outwards to the edges of the nutrient surface. 2. On inspissated blood serum the growth was as on agar, but more luxuriant and rapid. 3. On gelatin (stab) a typical "nail" growth was produced; the head, elevated and spherical, soon became yellowish and porcelain-like in appearance, whilst the needle track in the depths of the gelatin was occupied by numerous small, spherical, discrete yellowish colonies. No liquefaction of the medium took place. 4. On gelatin (shake) an abundant evolution of gas took place. 5. In litmus milk a good growth took place, accompanied by the production of an acid reaction; coagulation of the casein was accomplished in from three to five days. 6. On potato a thick, yellowish-brown, viscid layer rapidly made its appearance, the colour deepening with age. Numerous bubbles of gas were seen to be entangled in the growth. From a consideration of these properties it seemed most probable that we were dealing with the pneumo-bacillus of Friedländer, and in order to confirm this opinion a small quantity of a twenty-four hours old agar culture was removed from the tube with a platinum spatula and introduced into the subcutaneous tissue at the root of the tail of a mouse weighing 20 grammes. Death ensued in forty-eight hours, and at the post-mortem examination the heart-blood was found to be crowded with the capsulated Friedländer's bacillus. On several subsequent occasions cultures were made from the conjunctival secretion and from the material on the caruncle, with precisely similar results. Some of the actual material removed from the caruncle was also inoculated into the subcutaneous tissues of another mouse. Death followed in three days, and the Friedländer's bacillus was recovered from the heart-blood.

I am indebted to Dr. Brailey for permission to publish the notes of the case.

LEICESTER GENERAL INFIRMARY.

A CASE OF PERFORATED GASTRIC ULCER; OPERATION; RECOVERY.

(Under the care of Dr. J. ST. THOMAS CLARKE.)

THE following case, though simple throughout, gives additional evidence of the extreme value of early accurate diagnosis and promptitude in action on the part of the general practitioner, supplemented by abdominal exploration almost immediately applied after admission of the patient into hospital. In the last edition of the work on "Abdominal Surgery" by Mr. Greig Smith[1] it is stated that altogether about 100 operations have been performed for perforating gastric ulcer, the death-rate, as near as can be judged, being for the acute cases about 70 per cent., and for the chronic cases about 55 per cent. This is high, but it is better than would be got by leaving the cases to nature, where the mortality is over 90 per cent. With its present mortality operation is already fully justified—indeed, operation immediately on the diagnosis of perforation is nothing less than imperative. The extensive

[1] Vol. i., p. 570.

Hosted by Google

diffusion of the gastric contents only six hours after perforation is a noteworthy point in this case.

A domestic servant, aged nineteen years, was seized with severe epigastric pain and sickness two hours after her mid-day dinner of beef, potatoes, and rice pudding—namely, about 4 P.M. She had had some uneasiness about the stomach for two or three days previously, and two years ago she had suffered from hæmatemesis and since then had often felt pain after her food with occasional sickness. Dr. Davies of Aylestone Park, Leicester, on being called to see her at once suspected perforation of the stomach and promptly telephoned to the hospital to ensure immediate attention on arrival. On admission (Nov. 11th, 1896) at 8.30 P.M. the patient was collapsed, though not markedly so, but her symptoms were clearly abdominal, and her aspect, attitude, and pallor made it evident at once that abdominal exploration was urgently called for. The operation was commenced at 10 P.M. by a five-inch median incision from close to the xiphoid cartilage to near the umbilicus. The left rectus was not divided. The falciform ligament of the liver being in the way somewhat delayed the due opening of the peritoneum, but on getting through this membrane odourless gas and turbid fluid escaped, and bits of potato and rice were seen scattered about. There were no adhesions. On drawing down the stomach a perforated ulcer the size of a threepenny piece was found on the anterior surface near the cardiac end, through which some more rice and potato were found escaping. The edges of the ulcer were indurated and the base around for some distance was thickened. Considerable traction downwards was necessary to bring the ulcer within due reach. The fluid and bits of food were as far as possible at once removed, sponges were adjusted around, and the stomach was washed out with two syringefuls of fairly hot water. The edges were too deep to admit of being trimmed, so the opening was now closed by two rows of fine silk sutures by Lembert's method and fixed well beyond the ulcer both above and below. The abdominal opening was then covered temporarily with hot sponges and a second median incision was made a little above the pubes so as to explore Douglas's pouch. On passing a good-sized sponge deep into this it was found on withdrawal to be soaked with the same turbid fluid as noticed previously. The abdominal cavity was now freely irrigated with hot water at a temperature of 105° F., several pints being passed through it, and the various recesses especially were dealt with by means of the glass tube passed between the coils, above and under the liver, and in the different regions till all fluid returned clear. The surplus was then sponged away. A large drainage-tube was then inserted into Douglas's pouch and the lower wound was closed and a similar piece of tube was inserted through the upper opening and reaching to the site of the ulcer. The operation lasted one and three-quarter hours and was borne well by the patient. Three hours after the operation a hypodermic injection of morphia was given to relieve pain. Sickness occurred once in the night. Nutrient enemata were administered regularly. On the second day improvement was noticed. Thirst was relieved by a hot-water enema each day and the drainage-tubes were removed and replaced by plugs of iodoform gauze. On the sixth day a small discharge of pus occurred from the epigastric wound, which otherwise was doing well. Rectal feeding was continued till the eighth day, when the patient started with small sips of hot water and with half-teaspoonful doses of Brand's essence. The wounds gradually closed and convalescence was uninterrupted, and the patient was discharged well on Jan. 13th, 1897, weighing seven pounds more than on admission.

Remarks by Dr. CLARKE.—There seems to be no doubt that in this case, apart from early operation and efficient suturing, the free irrigation of the abdominal cavity must have been an essential factor in the success. Mere sponging alone, as practised by some, could not be relied upon to clear away all the traces of the fluid which had escaped from the stomach and which must have bathed more or less before the operation the whole peritoneum. Further, the second opening must have been a great contributory also to the well doing, as Douglas's pouch contained a quantity of the gastric fluid, and to have been content with irrigation and sponging out apart from a second opening would have left a quantity of this fluid unreached. Another point is, whether good is done by syringing out the stomach. If time admit this process would help to clear it and to dilute any contents likely to irritate a newly sewn wound. The heat of the irrigating fluid is apparently very beneficial if done at a temperature over 100°, and probably Greig Smith's suggestion of employing irrigation during the whole operation will often be of advantage to the patient, though not adopted in this case. I have to thank very greatly Mr. M. B. Foster, the house surgeon, for his assiduous attention throughout the case and for putting together the details for publication.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

"Sable Intestinal."—Gummatous Enlargement of the Kidney. — Minute Anatomy of Intussusception. — Giant-celled Tumours of the Skin.—Occlusion of the Duodenum.

A MEETING of this society was held on March 16th, Mr. A. E. BARKER, Vice-President, being in the chair.

Mr. S. G. SHATTOCK made a communication on "Sable Intestinal." He described the "sand" as consisting almost solely of spheroidal aggregations of vegetable sclerenchymatous cells, about half a millimetre in diameter, in all ways like those so well known to occur in the fruit of the pear. They were quite free from adventitious crystalline deposits. A closely similar case brought before the society in 1892 by Professor Delépine appeared to have been the first, and up to the present time the last, recorded in this country. Professor Delépine's case more closely corresponded with the original description of Laboulbène (1873) in that the cell islets were admixed with crystalline depositions of phosphate, oxalate, and carbonate of calcium. The patient from whom the specimen was obtained was a woman aged forty-five years, under the care of Mr. A. E. Hind of Jersey, who had suffered for about seven years with left hydro-nephrosis. She visited Vichy a few years ago, where the sandlike material passed by the bowel was thought to come from the kidney by some fistulous communication. After an aperient she frequently passed as much as two ounces of the "sand." The patient was fond of pears and these were the only articles in her dietary capable of furnishing it. The accumulation of orange pips and fruit stones, &c., above intestinal strictures was well known, but an explanation of the retention of such minute residua was not easy. In the case recorded the pressure of the hydro-nephrotic kidney may have led to obstruction sufficient to retard the progress of the indigestible materials. The term "sable intestinal" should not, Mr. Shattock remarked, be applied to biliary gravel, which is at times passed in considerable quantity by the intestine.—Mr. BARKER asked if the discharge of the vegetable débris was continuous and if the grains floated in water.—Mr. SHATTOCK, in reply, said that the discharge was intermittent, but that its appearance could always be brought about by giving an aperient. The grains sank in water.

Mr. A. A. BOWLBY exhibited a specimen of Gummatous Affection of the Kidney causing a large renal tumour. The patient was a stout, healthy woman, forty years of age, who had suffered from syphilis twenty-one years previously, but had had no syphilitic manifestations for nineteen years. She complained of a tender swelling in the right lumbar region, which steadily increased in size. There were no other symptoms, and except for an occasional trace of albumin the urine was normal in amount and composition. The swelling attained such a size that it simulated a large new growth of the kidney, and was removed by lumbar nephrectomy. It weighed over a pound, and was found to be a kidney so completely infiltrated with gummatous growth that it was almost impossible to find any trace of the renal tubules, and as its removal was not followed by any diminution of the quantity of urine it is almost certain that it was not functionally active. Two years after the operation the patient was in excellent health, and there was every reason to believe that the other kidney was sound. The condition did not appear to have been hitherto described. — Mr. BERTRAM ABRAHAMS referred to the case of a child, six months old, the subject of congenital syphilis, in which there were gummata causing nodular protrusions.

Mr. D'ARCY POWER brought forward a series of lantern slides to illustrate some points in the Minute Anatomy of

Hosted by Google

Intussusception, saying that he did so partly to obtain the benefit of criticism and partly because some of the specimens from which the sections were taken had already been shown at previous meetings of the society. After drawing attention to the fact that adult intussusceptions were often associated with polypi, Mr. Power showed some sections taken from a case of intussusception exhibited by Mr. Lockwood in 1892. The specimen was obtained from a woman who died shortly after an abdominal section and enterectomy for the relief of intussusception of five days' duration. Microscopical examination showed that the intestine had undergone very chronic changes, for the villi had become converted into mere tags of connective tissue, whilst all the coats of the intestine had been chronically inflamed. Other sections were taken from a specimen brought before the society by Dr. Peacock in 1864. The case from which the specimen was obtained occurred in the practice of Mr. Hacon of Hackney, to whom Mr. Power expressed his gratitude for additional information. The original specimen consisted of a piece of intestine measuring forty inches in length, which had been passed by a woman aged thirty-two years. It was voided without any blood, but enveloped in fæcal matter on the eighteenth day after the onset of severe intestinal obstruction. The patient died unmarried on July 30th, 1889, from some lung trouble, but she never again had any acute intestinal symptoms, though she was subject to constipation. Microscopic examination showed that all the coats of the intestine had undergone sclerosis. The line of the mucous membrane was distinct, though none of the details of its structure could be seen; but the sub-mucous coat was indistinguishable from the muscular, and the muscular layers from each other and from the serous layer. The whole thickness of the section consisted of dense fibroid tissue, like that found in an old scar. Mr. Power then demonstrated, by means of sections taken from other cases in which pieces of intussuscepted bowel had been passed and the patient had recovered, that the intestine might undergo a process of tryptic digestion before it was extruded. He then showed sections from a case of double intussusception which he had exhibited before the society in 1886. One of the intussusceptions was of the ordinary ileo-colic type and presented the changes usually found in acute invagination; the other was retrograde and colo-colic. It had been formed much later than the ileo-colic invagination, and Mr. Power thought that it had been produced when the child was so exhausted that the wall of its alimentary canal hardly responded to the effects of pressure. The slight congestion of the bloodvessels in the sub-mucous tissue and the great enlargement of the vessels in the serous coat and in the mesentery showed that the patient was not absolutely moribund when the second intussusception was formed.—Mr. SHATTOCK suggested that some of the spaces shown in the microscopic specimens might be dilated lymphatics.—Mr. BARKER asked if in any of the severe cases there was total destruction of the mucous membrane. He thought that there was great variation in the amount of change in the gut in different cases, quite apart from the time that the intussusception had existed, just as was the case in strangulated hernia.—Dr. COUPLAND asked if Mr. Power could say how long the intussusception had been down before the tryptic digestion began.—Mr. TARGETT asked whether the detachment of an intussusception was due to sloughing or to digestion. Could this digestion be the cause of the passage of tubular casts of the intestinal mucosa?—Mr. BOWLBY remarked that the cases of recovery quoted after sloughing of the intussusception had been in adults. He thought that this was a much rarer accident than the text-book description would indicate, and that in children it was scarcely ever recovered from.—Mr. SPENCER asked whether in Mr. Power's experiments the digestion had been purely tryptic in an aseptic medium, or whether organisms had been present as well.—Mr. POWER, in reply, said that his specimens had not been taken from very severe cases. Tryptic digestion had been performed in the presence of organisms, just as in the normal intestine.

Mr. TARGETT read notes of four cases of Small Tumours removed from the Integuments. They were well-defined tumours situated beneath the skin, and in two instances definitely above the deep fascia. Microscopically they were characterised by possessing an abundance of polynuclear giant cells, the nuclei being crowded into the centre of the cell, and not arranged in a peripheral ring as in tuberculous giant cells. The questions of malignancy and their probable origin were discussed. In one of the cases recurrence had taken place; there was no history of syphilis to be obtained in any of the cases, and the microscopic appearances did not suggest it.—Dr. GALLOWAY said that he had recently seen a very similar tumour, which was in the precubital space, and was one of several subcutaneous tumours. It was removed for diagnostic purposes, and was found to contain many giant cells, but no tubercle bacilli. After a time an enlargement of one testicle occurred and iodide of potassium was administered. This not only led to the disappearance of the testicular enlargement, but also to that of the subcutaneous tumours, which he therefore thought must have been syphilitic. There was a history of syphilis in the case.

Dr. F. H. CHAMPNEYS and Mr. D'ARCY POWER exhibited a specimen showing Occlusion of the Duodenum by a complete Transverse Septum. It was taken from an infant who lived for five days and who had vomiting and jaundice from birth. The lumen of the intestine was found to be completely interrupted by a septum stretching across the second part of the duodenum, just before the entrance of the common bile-duct. A microscopic examination by Mr. Strangeways Pigg showed that it was a direct continuation of the mucous, sub-mucous, and circular coats of the intestine. It was suggested that it had been the result of some error in the developmental processes connected with the formation of the liver.—Mr. SHATTOCK agreed with this view of the pathology of the condition, and observed that a similar stenosis of the œsophagus had been known to occur at the point at which the outgrowth of the lung had originally occurred.—Mr. W. G. SPENCER objected that there was no abnormality in the liver or spleen in this case. He suggested that the abnormality might be due to some deformity taking place at the upper part of the neck of the umbilical vesicle.—Mr. RAYMOND JOHNSON thought that the cases were on a par with stenosis of the intestine at the level of Meckel's diverticulum, with stenosis of the aorta at the point of entrance of the ductus arteriosus, and possibly with imperforate anus.

OPHTHALMOLOGICAL SOCIETY.

Discussion on Retro-ocular Neuritis.

AN ordinary meeting of this society was held on March 11th, Mr. E. NETTLESHIP, President, being in the chair.

Mr. MARCUS GUNN, in opening the discussion on Retro-ocular Neuritis, referred the disorder to a group of diseases which, though not recognisable by objective features, had distinct clinical manifestations, and on account of its subjective aspect was liable to be confounded with hysterical amblyopia, particularly when one eye only was affected. An important distinction between the two conditions was furnished by the reaction of the pupil, which was active in the hysterical condition, but sluggish or absent in the nerve affection, there being sometimes failure in maintaining the contraction. Occasionally the papilla was affected and in some cases both eyes were involved, but the changes in the disc were never gross. In papillitis the fundus changes preceded the loss of vision, but in retro-ocular neuritis vision failed early and in the centre of the field, the disc changes occurring later. Vision improved with subsidence of the neuritis, which might be followed by some pallor of the outer half of the disc proportionate to the intensity of the inflammation. It appeared that the swelling in papillitis did not interfere immediately with the transmission of nerve impulses, whereas in deeper seated neuritis it did so immediately, owing to the pressure being exerted centripetally upon the nerve fibres. This he attributed to the resistance of the nerve sheath, pointing out that the effect was most marked when the portion of nerve affected lay within the optic foramen, which was quite unyielding. One of the most prominent features of the disease was the presence of a central scotoma, first for colour (green-red) and afterwards for light, showing that the macular fibres were earliest affected. This might be due to the following facts: 1. The macular fibres, though peripheral at the ocular end of the optic nerve, attain a central position in the optic foramen. 2. The macular fibres, being functionally the most active, are earliest affected by pressure. 3. The principal lymph current traverses the centre of the nerve. 4. The macular fibres

Hosted by Google

occupy a relatively large area in the optic nerve. With regard to the symptoms of retro-ocular neuritis, in one case there was subjective sensation of colour of a violet or reddish pink tint, with slight peripheral contraction of the field and a diminution there of perception for green, which assumed a bronze appearance. The movement of the eyeball was painful in one or other direction corresponding with the portion of nerve affected. The degree of amblyopia varied greatly. Acuity of vision was diminished in a bright light or after prolonged use, general fatigue, or exhaustion from want of food. In some cases objects appeared as if seen through a moving haze. These phenomena might be explained by the breaking up of the nerve-sheath, leaving the axis cylinders incompletely insulated, or by the alternating activity of exhausted fibres. In support of this last suggestion it has been found that the colours red and blue are distasteful to the subjects of retro-ocular neuritis. The liability to injury appears to be more marked at the periphery and extreme centre of the nerve. The causation of the neuritis may be traced locally to the spread of the change to the nerve from neighbouring orbital cellulitis, due to erysipelas, cold, or septicæmia; or to periostitis extending to the optic foramen from the adjacent sphenoidal sinuses, in which case both nerves are affected; or the neuritis may be a local manifestation of a general disease, such as syphilis, gout, or rheumatism, the latter having a tendency to recurrence; and, finally, the optic tracts and nerves are liable to suffer as part of the central nervous system, as in insular sclerosis.

Dr. BUZZARD spoke on the medical group of cases exhibiting the features of retro-ocular neuritis. In insular sclerosis disorders of vision were frequently associated with atrophy of the optic disc, a condition referable to neuritis of the retro-ocular portion of the nerve; 50 per cent. of cases of this disease presented pallor of one or both discs, or in place of this a red-grey injection and amblyopia lasting for days or months. Post mortem there were found islets of gelatinous tissue of a warm grey colour, having a diameter of an inch or more in the brain, and varying greatly in number. Microscopically, they were found to exhibit naked axis cylinders, increase of the fibrous elements and a primary vascular change, but a certain proportion of the fibres were degenerated independently of the other changes. Dr. Buzzard attributed these appearances to interstitial inflammation occurring in local patches capable of resolution, but causing temporary paralysis, and he assumed the same condition to be present in the optic nerve. Secondary degeneration did not take place, the lesions were localised, and the pallor of the disc was due to interference with blood-supply, not to atrophy. The local diagnostic features were the pallor or greyish-white colour of the disc, chiefly in the temporal half, the edges being sharp, the physiological cup deep, and the lamina cribrosa distinct, these changes being bilateral and associated with preceding or immediate impairment of vision; whereas in the intra-ocular form of optic neuritis the changes were much more obvious and attended at first with little or no alteration in vision and no central scotoma, the loss of vision being slowly progressive. In the retro-ocular form the central scotoma was general and the peripheral amblyopia a characteristic feature, but both were transitory, and there was no progressive deterioration of vision. Concentric contraction of the visual fields sometimes occurred in diphtheria, and the speaker referred to an instance in a man, aged fifty-eight years, with paresis of arms, legs, and palate after sore throat, to whom the floor appeared concave at the point of sight. There was no scotoma, the fields of vision were small, and the left disc was pallid. The fields had since enlarged.

Dr. GOWERS drew attention to the modern established fact that an axis cylinder contained as many fibrils as there were fibres in a nerve, and the important bearing this had on the comprehension of pathological changes. In connexion with the rheumatic origin of neuritis he quoted an instance of a young man who, after a bath, suffered from paralysis of the ocular nerves with proptosis and tenderness of the left eye associated with convulsions, and followed by a similar condition on the right side. He attributed the symptoms to acute cellulitis of the orbit extending to the membranes of the brain. Referring to ten cases of insular sclerosis in which the optic nerve was affected there were none, he thought, in which the nature of the changes suggested an islet in the optic nerve. In many of the cases the state of the vision and appearance of the disc were identical with those occurring in tabes dorsalis, apparently a primary affection of the nerve fibres. The cases referred to by Dr. Buzzard he thought were of a similar nature. Retro-ocular neuritis was frequently a result of blood poison, especially gout. The symptoms might simulate those of an intracranial tumour affecting the chiasma.

Dr. BERRY thought the disease was a very obscure one, and that the diagnosis was made too frequently with little precision. The condition was distinct from papillitis of cerebro-pathological origin. Pallor and atrophy of the disc he considered were doubtful signs of retro-ocular neuritis. Symptoms very similar to those attributed to this disease occurred in connexion with irritation in the teeth and also in migraine where nothing could be found in the fundus. Toxin poisoning, he thought, was unlikely to produce changes in one eye only. He classified the forms of defective vision due to retro-ocular causes as (1) those connected with cerebral tumour; (2) those due to chill and for the most part unilateral; and (3) toxic amblyopia, which was bilateral and, he thought, not neuritis. Many cases diagnosed as hysteria were more serious cases of nerve or cerebral disease which manifested itself later.

Dr. HILL GRIFFITH said that, excluding tobacco amblyopia, he had met with twenty-seven of the cases under discussion, eight of which had been bilateral. The cases occurred between the ages of fourteen and fifty-seven years. There was a central scotoma in nearly all, and no contraction of the field of vision. A direct light reflex was present, though in three cases there was no perception of light. The vision and pupil reflex was ultimately restored in all the cases. Pain occurred early only, and was at its worst about the second day. The disc at this period was pale or unaltered. All the cases were treated with potassium iodide, salicylate of soda, and blisters, and recovery took place in all, though in some vision was not as good as before the attack. Dr. Griffith agreed with the suggestion of Thorburn, that the symptoms were due to rheumatic axial neuritis.

Mr. RICHARDSON CROSS, referring to the literature of the subject, said that central scotoma and slight pallor of the optic disc appeared to be the most widely observed features. Out of fifty-seven cases of retro-ocular neuritis he had selected from 154 instances of optic nerve disease the disorder was attributed to toxic causes in two-thirds, which was more common than in his own observations. Uhtoff in 400 alcoholic subjects observed pallor of the disc in seventy; half he attributed to alcohol and one-sixth to tobacco, the choice of these among the remaining third being uncertain. He considered alcohol was an important factor in the causation of the condition, though it was asserted by some that the occurrence of tobacco amblyopia was prevented by its use. In his own five cases there was slight papillitis in one eye with a central scotoma, but no affection of the periphery and no other ocular changes.

Mr. LITTLE, speaking of these cases apart from toxic causes, dwelt upon the occurrence of pain, central scotoma, and diminution of visual acuity as characteristic of the affection in the absence of definite fundus change. Though the scotoma was large and in one case there was absolute blindness, all the cases recovered rapidly.

The discussion was adjourned till Wednesday, March 24th.

EPIDEMIOLOGICAL SOCIETY.

Review of the Statement of the Dissentient Members of the Royal Commission on Vaccination

A MEETING of this society was held on Feb. 19th, Mr. SHIRLEY F. MURPHY being in the chair.

Dr. J. C. MCVAIL read portions of a paper (printed copies of a proof of which were supplied to all present) reviewing the Statement of the Dissentient Members of the Royal Commission on Vaccination. He inferred from their use of such expressions as "*more* effective, *more* practicable, and *less* objectionable modes of protecting the community from small-pox than by vaccination," "approaching the subject *too exclusively* from the standpoint of vaccination," and "according *too little* importance to other measures," that when they did not by their silence imply agreement they differed from the conclusions of their colleagues more in degree than in fact. Their treatment of the early history of small pox, their estimates of the extent and influence of the practice of inoculation, and their arbitrary choice of authorities, though not matters of much practical importance, were in the

Hosted by Google

highest degree unsatisfactory from the bias they displayed. Mead, for example, was not, as they suggested, prepared to apply to what he expressly described as "the more common contagion of small-pox" the strict quarantine and isolation that he advised as precautions against future re-introduction of the plague, the two diseases being looked on in his days somewhat as cholera and measles are now; and (to say nothing of their protests against compulsion as applied to vaccination) it was unfair to italicise in a quotation from Haygarth his reference to the benefits "which might reasonably be expected from the united, systematic, and concerted regulations of the whole island, aided and strengthened by legal premiums and punishments," without a hint of his belief that the infection could not be conveyed by clothing or otherwise than by actual contact, on which the feasibility of his scheme depended. It was even more unfair to represent Sir James Simpson as a supporter of isolation as a substitute for vaccination on the strength of selected passages from an essay which contained a glowing eulogy of Jenner and vaccination. They seized every opportunity of emphasising the influence of sanitary improvements in reducing the mortality from "fevers," though the figures they quoted from Sir John Simon showed that between two periods 1746–55 and 1846–55 selected by them "fevers" had declined in the proportion of 100 to 71 only, but small-pox of 100 to 17, and that in recent years the reduction had been confined to typhus fever and typhoid fever, measles having been unaffected, and there was no falling off in scarlet fever until 1880. Their speculations as to the numbers of susceptible persons and the influence of inoculation and vaccination at different periods were based largely on conjecture and assumption. Their account of the labours of Jenner, of his controversy with Woodville and Pearson, of their conversion to his views as to the non-eruptive nature of cow-pox and of their employment of the "variolous test," was misleading. They seemed to desire to charge Jenner with deliberate fraud, as using for his tests clear variolous lymph instead of pus in order to court failure; when, in fact, with the instinct of a bacteriologist, he did so that he might have the virus free from extraneous contamination. When it suited their purpose they described as vaccinations operations which they had previously declared to be almost certainly variolations, and endeavoured to extricate themselves from the dilemma by saying that they employed the word vaccination in a colloquial sense. They took the statistics of the Highgate Hospital—which for many years had been a small-pox hospital in name only, admitting none but paying patients, and refusing all under seven years of age—as fairly representing the extent of vaccination and the prevalence and age incidence of small-pox in London generally, wholly ignoring the evidence before them derived from the free hospitals of the Asylums Board at Homerton and Fulham, where of 2540 children admitted under ten years of age 47 per cent. were unvaccinated, though the proportion of unvaccinated children in London must have been incomparably less. When they came to the question of the recent epidemics at Sheffield, Leicester, Dewsbury, Warrington, and Gloucester there was the same effort to explain away positive facts and figures by arbitrary conjectures, and they refused to recognise differences in the type and severity of the disease, although they had argued that when vaccination was unknown the fatality varied from 2·5 to 33 per cent. They compared the death-rate of 9·9 per cent. among the vaccinated at Gloucester with that of 12 per cent. among the unvaccinated at Leicester, ignoring the fact that at the former town the disease was of the severest and at the latter of the mildest type, the fatality among the vaccinated and unvaccinated respectively having maintained the same relative proportions—viz., at Leicester, 1 and 12; in London, 2·2 and 24·2; at Dewsbury, 2·6 and 25·1; at Sheffield, 4·8 and 49·6; at Warrington, 6·4 and 35·3; and at Gloucester, 9·9 and 40·9. In the whole of the six towns the fatality among the vaccinated under ten years was 2 7 per cent. and of those above about 5 per cent. Among the unvaccinated under ten it was 36 per cent. and over ten 34·3. As to severity of type of small-pox, they affected to discredit Dr. Barry's classification of the cases into varioloid, and discrete, coherent, and confluent variola, which gave attack percentages among the vaccinated of 35·5, 50·0, 13·0, and 1·5, and among the unvaccinated of 0 0, 17·9, 62·5, and 19·6, on the ground that no two observers would exactly agree; but ignored the simple grouping by different men into milder and severer, which alike at Sheffield, Dewsbury, Leicester, and Warrington showed an almost exactly inverse proportion among vaccinated and unvaccinated. They refused, too, to recognise degrees of efficiency in vaccination, and took susceptibility to re-vaccination as indicative of the same to small-pox infection, although they knew that inoculation could be repeated. They affected to ascribe much of the great mortality from small-pox, especially among children, in the last century to the practice of inoculation, ignoring the Geneva statistics of a still earlier period, which showed that of 25,349 deaths, 6792 occurred in the first, 5416 in the second, 4116 in the third, 2826 in the fourth, and 1928 in the fifth, or 21,078 = over 83 per cent. in the first five years of life, and manipulated Dr. Ogle's statistics to suit their own ends, so that, e.g., in the *Contemporary Review* Mr. Picton spoke of the difference between 46·7 per cent. and 30·3 per cent. as 16·4 per cent. when vaccination was involved, but in the Statement of Dissent he held that the difference between 6·4 per cent. and 3·4 per cent. was 46·9 per cent. (by taking the 6·4 as the centum) instead of 3 per cent. when the reduction could, they fancied, be ascribed to "sanitation." The influence of sanitation was, they maintained, most evident in the early years of childhood. Well, said Dr. McVail, what could we learn from the case of Scotland, where vaccination was since 1863 compulsory at the age of six months? In the nine years preceding the passing of the Act 139 of every 1000 deaths from small-pox occurred in the first six months of life, and in the twenty-four years following 138. In the next six months the deaths in the former period were 153 and in the latter 47 in the 1000. The saving of 106 was clearly due to vaccination, and that of 1 per 1000 in the first half-year of life might be to sanitation. In Germany, again, where vaccination was not required until some time in the second year, 410 deaths per 1000 at all ages occurred in the first two years of infancy, and yet opponents of vaccination alleged that it was sanitation, not vaccination, that had reduced German small-pox. At Sheffield, which, according to the dissentients, was an insanitary though fairly vaccinated town, 25·6 per cent. of the deaths from small-pox were those of children under ten years; while at Leicester, unvaccinated, but relying on its boasted sanitation, the children constituted 71·4 per cent. of the whole mortality. The like ratio between the practice or neglect of vaccination of late and the small-pox incidence on the child population might be traced in every town for which the data were available; and yet they could not, while justly insisting on the susceptibility of childhood to the influence of surroundings for good or ill, recognise another and dominating factor in the mortality from small-pox. As regards the relation between variola and vaccinia the dissentients were in hopeless confusion: they failed to distinguish between the attenuated variolous lymph of Walker and Thiele and the variola-vaccine of Ceely, Voigt, Haccius, and others who had completely refuted the doctrine of the Alfort school, and they invoked Creighton and Crookshank alike, regardless of the fact that these gentlemen were essentially opposed to each other in their views, Dr. Creighton denying the venereal origin of vaccinal syphilis and substituting for Dr. Crookshank's bacteria a transcendental hypothesis of "memory" in diseases. On the vexed question of diseases communicated by or consequent on vaccination the Commissioners, as the result of inquiries conducted by their request into every alleged case during the past seven years, came to the conclusion that the dangers, though real as regards erysipelas and wound infection, had been greatly exaggerated and were practically insignificant. Mr. Picton and Dr. Collins thought otherwise, though abandoning the position of Mr. Hopwood, who ascribed to vaccination diseases that seemed to be on the increase, revising his list from time to time on no other ground than that some which had been supposed to be increasing were really found to be decreasing. The dissentient Commissioners relied largely on syphilis and erysipelas, but here again Dr. McVail confronted them with statistics from Scotland and the town of Leicester. In the nine years preceding the enforcement of vaccination in Scotland children in the second half-year of life contributed 109 out of every 1000 deaths from syphilis, and in the subsequent periods 1864–75 and 1876–87 the proportions were 118 and 109, or about the same; whereas in the first or unvaccinated half-year of life the number had risen from 575 to 612 and 647, so that unvaccinated infants contributed two-thirds of the total deaths from syphilis at all ages. In Leicester the mortality from syphilis, of course mainly infantile, had in the past

Hosted by Google

twenty years increased by 69·3 per cent., but in England and Wales generally by only 24·7 per cent., and from erysipelas by 41·5 per cent. in Leicester, as against a decrease of 16·7 per cent. elsewhere. The vagueness of the term "sanitation," under which they appeared to include progress in the comforts and decencies of life as well as all preventive measures—with the exception of the greatest of all, vaccination—enabled them to refer any improvement at any period back to the Middle Ages to this panacea, and by associating small-pox with typhus fever, "gaol fevers," and typhoid fever the strongly marked effects of vaccination on the small-pox mortality were merged in the more gradual improvement in the public health properly ascribed to the introduction of better habits and more wholesome surroundings; though why they should fix on the year 1800 as the era of "greater sanitary activity"—a period marked by no appreciable change in the law or the habits of the people, except the epoch-making introduction of vaccination—was by no means obvious. They quoted the belief or hope expressed by Sir E. Chadwick that improved sanitation would tend to the extinction of all preventable diseases, including small-pox, forgetting that, however deserving of our gratitude and respect he might be as a pioneer in sanitary reform, he was not a physician and had no right to pronounce on questions of a strictly medical character. Their treatment of Hirsch was peculiar, for they professed to agree with him that small-pox as well as typhus fever "took up its abode most readily in those places where the noxious influences due to neglected hygiene made themselves most felt," while making no reference to his declaration that "the achievement of Jenner was at once a turning point in the history of small-pox and a new era in the physical welfare of mankind," ..... and that "it could be only folly or stupidity that would seek nowadays to minimise or question the immortal merits of Jenner." Social position as well as sanitary environment had, they stated, a potent influence on the prevalence and fatality of small-pox; but that was mainly because the upper classes availed themselves of the protection afforded by vaccination, for, as Simon reminded us, several of the royal families of Europe, as the Stuarts, the House of Orange, and those of Austria and Germany, France and Russia, in the seventeenth and eighteenth centuries had many victims to this disease. The observation of Dr. Cross, that "the epidemic at Norwich in 1819 was almost exclusively confined to the very lowest orders of the people," was quoted as supporting their contention, but his explanation of this incidence—that "the indifference of the uneducated or badly educated was such that the number who availed themselves of the offer of vaccination was trifling"—was, as usual, ignored. With a strange confusion of cause and effect they ascribed to the increased facilities for isolation the decline of small-pox in London during the last five-and-twenty years, remarking that in 1871–2 only 31 per cent. of the deaths took place in hospitals, while in 1893 the proportion was 87 per cent. But they did not note that the total deaths were respectively 9657 and 206, and that the isolation of the 87 per cent., or 179, was far easier than that of the 31 per cent., or 2994. Dr. Russell of Glasgow had written to Dr. McVail complaining bitterly of the use made by Mr. Picton and Dr. Collins of the statistics of that city, in attributing the successful stamping-out of small-pox to isolation and sanitary reform; whereas he had distinctly maintained that, in his opinion, hospitals could not be looked on as more than auxiliary means, and were, perhaps, not without a certain amount of danger to the public, but that vaccination and re-vaccination had been carried out in Glasgow to an extent probably unparalleled elsewhere, so that the common lodging-houses and casual wards were for a time almost converted into vaccination stations. The dissentients formulated their scheme for the protection of a community, recommending early notification, ample hospital accommodation, vigilant house-to-house inspection, prompt removal of patients, supervision and quarantine for the most part in special stations, of persons exposed to infection, the disinfection or destruction of clothing, &c., closure of schools, inspection of tramps, and other precautions, as well as compensation to persons for damage sustained by quarantine, &c. Did they, he asked, realise the cost, the hostility that such interference with the liberty of the individual would evoke from the people who had conscientious objections to compulsion of any sort, and the risks of evasion, of concealment, and of failure in early diagnosis? Perhaps they did, for in recommending the retention, "in deference to popular belief," of the entire existing machinery for vaccination and the supply of lymph "they seemed to have more faith in vaccination and less faith in isolation than they were willing to admit even to themselves."

Brigade-Surgeon-Lieutenant-Colonel PRINGLE wished that the anti-vaccinationists could see what he had seen in India in epidemics of small-pox—the ground strewn with rotting corpses, incomparably more ghastly than in the case of cholera, when they lay calmly like Sennacherib's hosts; or districts where 90 per cent. of the population were hideously marked, while in others, where vaccination or the perfected system of attenuated inoculation had been long practised, the faces of the people were as unmarred as in this country.

Dr. ACLAND, in his inquiries into alleged injury from vaccination, had found none that would bear investigation. As to syphilis the disease had always been congenital, and erysipelas was invariably a post-vaccinal wound infection; there was no evidence of the transmission of tubercle, and in the very few alleged cases of leprosy and lupus the existence of the disease in the vaccinifer was a groundless assumption.

Dr. COUPLAND remarked on the difficulty of providing sufficient accommodation for isolation, and showed some instructive graphic representations of the age incidence and fatality of small-pox on the vaccinated and unvaccinated in Leicester, Dewsbury, and Gloucester.

Other speakers followed, and the discussion was continued until a late hour.

HUNTERIAN SOCIETY.

Exhibition of Specimens.

AN ordinary (pathological) meeting of this society was held at the London Institution on March 10th, Dr. G. E. HERMAN, President, being in the chair.

Dr. ARTHUR DAVIES showed a Heart taken from a girl eight years of age, which exhibited a marked condition of Malignant Endocarditis affecting the mitral valve and part of the left auricular wall. Infarcts were found in the spleen and kidneys.

Dr. SCHORSTEIN showed the Heart of a man, aged forty-one years, in which the mitral and posterior aortic valves were affected by Malignant Endocarditis. There were infarcts in the kidneys, but no albumin or blood at any time was found in the urine. Infarcts were found also in the left middle cerebral artery and the superior mesenteric artery, with an aneurysm which had burst into the peritoneal cavity.—Remarks were made by the PRESIDENT, Dr. SEQUIERA, Dr. ADAMS, and Dr. F. J. SMITH.

Dr. SCHORSTEIN also showed a specimen of Acute Colitis with Perforation in the Sigmoid Flexure. The patient had pneumonia, with an alcoholic history. The bacillus coli was not found in the colon, but was present in the lung.

Mr. TUBBY quoted a case of Rice-water Stools followed by a very foul empyema.

Dr. T. GLOVER LYON showed a Kidney affected with Miliary Tubercle taken from a patient with severe heart disease. There was no deposit in the lungs, but between the bladder and the rectum a deposit was present.—Remarks were made on the relation between heart disease and tuberculosis by Dr. HINGSTON FOX, Dr. SCHORSTEIN, Dr. A. DAVIES, and Dr. LYON.

Dr. PERKINS showed a Stomach with Ulceration Opening into the Splenic Artery, causing Fatal Hæmorrhage, in a woman aged sixty-six years.

Dr. F. J. SMITH showed a specimen of Tuberculous Meningitis taken from a girl, where there was entire absence of symptoms with the exception of rather severe headache at the onset, mental dulness passing into coma, and great activity of the knee-jerks. He also showed a specimen of Tumour of the Brain, situated at the base and involving the corona cerebri and the right optic tract. There was no observable symptom till within thirty-six hours of death.

SOUTH-WEST LONDON MEDICAL SOCIETY.

Acute Inflammation of Bone in Children and Young Persons.

A MEETING of this society was held in Wandsworth on March 10th, Dr. BENJAMIN DUKE being in the chair.

Mr. EDMUND OWEN gave an address on a Common and an Acute Inflammation of the Bones of Children

Hosted by Google

and Young Persons which sometimes Escapes Recognition. He said that the disease he referred to was known as acute septic osteomyelitis, although it had been called by various other names. Everyone admitted the importance and danger of the affection. It was referred to by the late Dr. Bristowe in a paper written in 1862,[1] who pointed out its distinguishing features and stated that it was often mistaken for rheumatism. Chassaignac had also written about it in 1857, stating that its cause was obscure, but that it was possibly of a "scrofulous" nature. He had also said that it is essentially a disease of young people, and is "very rarely found over the age of seventeen." Mr. Owen next described the pathology of the disease. He showed how micro-organisms are especially prone to affect the junction of the diaphysis with the epiphysis in long bones, this being the point at which new and delicate tissue is formed and growth is most rapid. It is here that the disease in question almost always commences. The organisms may be introduced into the body by means of damaged food or impure air or water. They affect the tissue of the part described and there elaborate a poisonous ptomaine. Abscess rapidly follows, and the staphylococcus pyogenes aureus is always found. (Specimens were exhibited showing the morbid changes.) The disease is a common one; out of 165 cases collected by Mr. Owen 96 were in males and 69 in females, the figures working out at about five boys to three girls. In these 165 cases the femur was affected in 83, the tibia in 47, and the humerus in 20. Next in order came the fibula, and in still smaller proportions came the radius, ulna, clavicle, and os calcis. The chief predisposing causes are depression of the system, fatigue, and, above all, injury of the part. It is apt to come on in young recruits after a fatiguing march. The local symptoms are those of deep-seated acute inflammation, pain, great tenderness on pressure, early redness and heat of the surface, especially where the bone is thinly covered with muscle. The constitutional symptoms are those of fever due to absorption of ptomaines; there are headache, delirium, and high temperature, rigors in adolescents, and convulsions in children. Many of the subjects of the disease die quickly from pyæmia. The question of diagnosis is important, as the disease may be, and has been, very often mistaken for rheumatism and erysipelas. The characteristic points are (1) the part of the bone affected, and (2) the marked tenderness on pressure, even when there is no redness. In rheumatism the joint itself is affected, and not the parts above or below. In erysipelas all the local symptoms are superficial. In periostitis the same applies, and the shaft of the bone will probably be primarily affected rather than the end. The treatment is by early incision, and, whether pus be found or not, the bone should be drilled or gouged. In some cases (especially in infants) the adjacent joint is attacked, and it must then be laid open and irrigated. Occasionally amputation is necessary or the patient may die from acute septic poisoning. Other bones and joints are often secondarily affected, and Mr. Owen showed a case illustrating this in which the inferior diaphysis of the left femur was first attacked, then the right humerus, and subsequently the right knee-joint.

The PRESIDENT and Dr. GILBERT RICHARDSON having briefly thanked Mr. Owen for his address, the latter answered several questions put to him by members, and the meeting terminated.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Primary Tuberculous Tenosynovitis.—Pathology of Missed Abortion.—Sarcoma of the Forearm.—Exhibition of Specimens.

A MEETING of this society was held on March 10th, Dr. T. HARRIS, President, being in the chair.

Mr. THORBURN and Dr. MOORE showed specimens of a case of Primary Tuberculous Tenosynovitis removed by the former from the extensor aspect of the wrist. The disease had originated in the sheath of the extensor minimi digiti, which tendon was infiltrated and almost destroyed, while the sheath for the common extensor tendons was only secondarily invaded. Mr. Thorburn dwelt upon the importance of recognising "compound ganglion" as a tuberculous lesion and on the necessity for its careful excision, as well as upon the perfect functional result obtained in the hand thus treated. Although among children tuberculous tenosynovitis is more common in the ankle, in adults it generally involves the region of the wrist, the probable reason being that adults throw a far greater strain upon the latter joint than do children, hence also the comparative frequency of tuberculous disease of the wrist-joint itself in the adult as compared with the child. Macroscopically, the sheath presented a dark red, succulent appearance. It contained a small collection of fluid at its upper end and a single rice-body. The interior of the sheath was generally the seat of irregular fungosities and deposits of fibrin. Microscopically it corresponded closely with the descriptions of previous observers.

Dr. W. E. FOTHERGILL gave a demonstration on the Pathology of Missed Abortion. The changes which occur in ova retained in utero for several months after the death of the fœtus were demonstrated by means of drawings, photo-micrographs, and sections. When the fœtal circulation ceases the vessels of the placenta are rapidly obliterated, the fœtal epithelium degenerates, and the maternal blood between the villi forms clots which are altered later into dense laminated fibrin. The decidual cells then multiply and invade the fibrin, which they gradually replace, filling the intervillous space with layers and bands of decidual tissue. At the same time the decidual cells disintegrate the fœtal epithelium, covering the chorion and its villi. This comes to be represented by scattered heaps and rows of nuclei, and finally disappears. The amnion remains almost unaltered, but adheres closely to the chorion, and the united membranes are thrown into folds and convolutions covering the rounded lobes of altered placental tissue. The fœtal portion of the placenta does not grow after the death of the fœtus, though the maternal portion containing the decidual cells remains active. It is therefore improbable that malignant new growths can arise from fœtal placental elements.

Mr. C. E. RICHMOND described a case of Sarcoma of the Forearm with malignant family history occurring in a girl aged nineteen years. The father's aunt died from cancer of the breast, and the father's brother died at the age of thirty-four years from tumour of the thigh, which developed after injury. Of the mother's sisters, one died at the age of sixty years from cancer of the face, which developed after injury, and another died from tumour of the womb. In the present case there was a history of less than five months' duration, in which, from a slight enlargement, the left wrist had reached nineteen inches in circumference. The tumour was a periosteal sarcoma commencing at the lower end of the radius. Microscopically it consisted of large spindle and large round cells.

Mr. RICHMOND also showed a specimen of an Unusual Condition of the Spleen. In life it had occupied almost the entire left half of the abdomen, but did not enter the true pelvis. There were no marked symptoms of leucocythæmia, though the blood showed certain variations from the normal, and no history of ague or of syphilis. At the necropsy the spleen was found to be enormously enlarged and to be enclosed at its upper and back parts and sides by a thick layer of very dense fibrous tissue, which, though not very vascular, contained bloodvessels, some of them of the size of the radial artery. The spleen pulp was hardly anywhere normal, and on section showed strands and stellate masses of similar dense fibrous tissue. Microscopically the lobules of the spleen pulp were seen to be separated and compressed by fibrous bundles. The growth surrounding the spleen was outside the capsule and consisted of simple fibrous tissue. The view was advanced that it consisted simply of "organised inflammatory deposit."

The following card specimens were shown:—

Dr. BRINDLEY: (1) Adventitious Spleens; and (2) Aneurysms Bulging into the Right Auricle and Rupturing into the Pericardium.

Dr. HARRIS and Dr. RITCHIE: Lung affected with Chronic Pneumonia and Bronchial Dilatation.

Dr. HARRIS: Chronic Capsulitis of the Liver and Spleen.

Dr. RAY: Aortic Aneurysm with Secondary Aneurysms of the Carotid and Subclavian after Ligaturing.

LIVERPOOL MEDICAL INSTITUTION.

Dacryocystitis.—Cases of Stone in the Bladder.—Hysteria in Gynæcology.—Folliculitis Decalvans.

A MEETING of this society was held on March 11th, Dr. A. C. E. HARRIS Vice-President, being in the chair.

Mr. EDGAR BROWNE opened the adjourned discussion on the Treatment of Dacryocystitis, the paper introducing the

Hosted by Google

subject having been read by Mr. H. E. Jones at the last meeting. Mr. Browne said that treatment must be founded upon a knowledge of physiological and pathological conditions and should aim at restoring the organ as nearly as possible to its natural state, but many of the methods in vogue violated these conditions. The canaliculi were capillary tubes and had purposely been made small by nature. If nature had designed a drain-pipe she would have made it larger. The collecting sac and discharging duct were potential tubes, capable of dilatation, but not habitually dilated. The inferior opening was exceedingly small. The apparatus was of the nature of a syphon, acting by suction and capillary attraction, and not simply by gravitation. The necessity of preserving the capillary character of the canaliculi had led him many years ago to suggest partial slitting of the wall. It was essential to preserve a portion of the tube, and not convert it into a gaping groove. He therefore used small probes and endeavoured not to overdistend the nasal opening, or, indeed, any part of the passages. Stricture was not a primary cause of obstruction, but the result of inflammation of the duct. The primary cause was bacterial infection of the lining membrane of the duct and the vascular structure surrounding it. His treatment by irrigation had stood the test of years. He would reserve the style only for exceptional cases where the structures had become distorted by long-continued inflammation.—Mr. H. E. JONES, in reply, said that the controversy as to the relative importance of inflammatory swelling or true stricture of the duct as causes of mucocele had been going on for nearly two hundred years. He was convinced that the prolonged use of probes and styles often irreparably damaged the canaliculus and occasionally caused stricture of the duct.

Mr. RUSHTON PARKER related in outline the clinical features of ten cases of Stone in the Bladder occurring in nine male patients. Four were subjected to lithotomy and four to lithotrity, whilst on one both operations were performed. Of the five cases of lithotomy two were boys aged eleven years. In one the lateral perineal operation was performed, and in the other the suprapubic operation. Both calculi were oxalate of lime. Two of the cases were men aged sixty-six and sixty-nine years respectively; both these calculi were phosphatic, with cystitis and ammoniacal urine and previous retention, due in one case to stricture and in the other to enlarged prostate. In the fifth case—a man, aged forty years—the stone was also chiefly phosphatic, with a nucleus of uric acid. In this case a calculus was found in the roof of the bladder a month after lithotrity had been performed. Of the five cases of lithotrity one was a man aged sixty-two years; the stone weighed three-quarters of an ounce. The patient returned to his home in a week and is now well. The next patient was forty years of age; the stone weighed a quarter of an ounce. After the crushing operation his symptoms were improved, but a month later lateral lithotomy was performed as stated above. The next patient was a man seventy years of age, from whose bladder a phosphatic calculus and about four inches of indiarubber catheter were removed by the lithotrite. The next case had an oxalic calculus weighing a few grains, and the last of the series had a phosphatic calculus formed round a nucleus of "chewing gum," a stick of which he had passed into his urethra.

Dr. IMLACH read a paper on the Place of Hysteria in Gynæcology. Following popular usage, he claimed that the term hysteria should only be applied to a special disorder of mental and physical development in girls and young women, and should not be extended to the functional neuroses of men.

Dr. STOPFORD TAYLOR showed a case of Folliculitis Decalvans in a man aged thirty years. The inflamed follicles occupied the outer two-thirds of the right thigh, surrounding a small bald pitted area the size of the palm of the hand. The disease had previously affected the corresponding region on the other limb, and the skin there was also perfectly bald.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Tubal Abortion.—Broad Ligament Cysts.—Anti-streptococcic Serum in Puerperal Toxæmia.—Vesical Calculi deposited on Silk Sutures.

A MEETING of this society was held on Feb. 24th, Dr. MALCOLM BLACK, President, being in the chair.

The PRESIDENT referred to the death of Sir Spencer Wells, one of the society's honorary presidents, and it was resolved to send an excerpt from the minutes to his relatives expressive of sympathy in the loss that they and the profession had sustained.

Dr. JENKINS read notes of three gynæcological cases from the Victoria Infirmary, Glasgow. The first was a case of Puerperal Fever, interesting chiefly from the fact that the great omentum was adherent to the parietal peritoneum, projected into the pelvic cavity, and formed the greater part of pelvic swellings on both sides of the uterus, which at the first examination under chloroform were believed to be inflammatory and of tubal or ovarian origin. Puncture in such cases was in the highest degree dangerous, and he believed that the radical vaginal operation was the only one that need be considered. The second case was one of Tubal Abortion. At the abdominal section the appendix vermiformis was found to be thickened and adherent; the right ovary was as large as a hen's egg and contained dermoid material, but showed a fresh corpus luteum in the small part of normal ovarian tissue left. The right ovary and tube and the appendix vermiformis were removed. The patient made a good recovery. The third case was one of Congenital Absence of the Portis Vaginalis Uteri and Patency of Gärtner's Duct.

Dr. EDGAR described three cases of Broad Ligament Cysts, in two of which he had performed abdominal section—in the one for a small intra-ligamentous cyst on the right side and a hæmatoma of the left ovary, and in the other for a parovarian cyst of the right broad ligament with matting together of the left ovary and tube, which contained pus. In his third case, in which there was a tense elastic mass posterior to the uterus and reaching from side to side of the pelvis, he operated through the posterior vaginal fornix. After curetting the uterus and amputating a rather large cervix with stellate laceration, he opened into the pouch of Douglas, punctured the cyst, pulled it down, and removed it.

Dr. A. W. RUSSELL reported a case of Puerperal Toxæmia with symptoms of Mania in which the anti-streptococcic serum had been used and recovery had followed.

Dr. RUSSELL also showed Fragments of Vesical Calculi removed from a patient upon whom Cæsarean section had been performed five years ago. Several of the pieces had as their nucleus a bit of silk suture and in one the knot was seen. This was the second case that had come under his observation.—Professor MURDOCH CAMERON, who had performed both of these Cæsarean operations, gave some account of the cases.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Bubonic Plague.

A MEETING of the Section of Pathology was held on Feb. 26th, Mr. J. B. STORY being in the chair.

In the absence of Dr. JOSEPH REDMOND, the sectional secretary (Dr. MCWEENEY) demonstrated Microscopic Preparations by Dr. Yersin of the Plague Bacillus discovered by himself (Dr. Yersin) and (independently) by Dr. Kitasato. One of the slides was a gentian-violet stained smear preparation from the bubo of a Chinaman who died at Hong-Kong from the disease, and showed enormous numbers of short oval bacilli in pairs and single forms, with an unstained spot in the centre like the bacillus of chicken cholera, lying amongst the lymphoid elements and pus cells. The other was a preparation from the blood of a mouse which had succumbed to septicæmia consequent on the inoculation of a pure cultivation of the bacillus. Here the organism took the shape of a diplococcus or very short diplo-bacillus. The speaker then gave a *résumé* of present knowledge of this organism, including its *habitat* in the soil, its tendency to attack rats, &c., through which its virulence became so heightened that it could attack the healthy human system, and the successful results claimed by Yersin for sero-therapeusis. He concluded by quoting a specimen of the directions said to have been issued by the Royal College of Physicians of London for the cure of plague during the last great visitation in 1665: "Pull off the feathers from the tails of living cocks, hens, pigeons, or chickens; and holding their bills, hold them hard to the botch or swelling, and so keep them at that part till they die, and by this means draw out the poison. It is good to apply a cupping glass, or embers in a dish, with a handful of sorrel upon the embers."—The communication was discussed by Mr. STORY and Dr. PARSONS, and Dr. MCWEENEY replied.

Reviews and Notices of Books.

Vita Medica; Chapters of Medical Life and Work. By Sir B. W. RICHARDSON, M.D., LL.D., F.R.S. London, New York, and Bombay: Longmans, Green, and Co. 1897. Pp. 496. Price 16*s*.

THERE is something very pathetic in the last chapter of this book taken in conjunction with the preliminary note prefixed by the author's son, which runs as follows: "These chapters of 'Vita Medica' were finished by my father on Wednesday, Nov. 18th, 1896, just before eight in the evening. At ten o'clock he was seized with the illness which ended fatally on Saturday morning, Nov. 21st." The last chapter commences: "But I must close somewhere, and it is at this point." Irresistibly on reading these passages the words of Thackeray rise to our minds: "Yet a few chapters more and then the last; after which, behold Finis itself come to an end, and the Infinite begun."

The book is in no sense an autobiography, but rather a collection of various reminiscences, set down just as they occurred to the writer, without any particular regard for order of time. In the first chapter Richardson relates how in his young days he met with a Dr. James Bird, and how the two attended a meeting at which sanitary questions were discussed. Richardson was "very plain in stating that we might by good management pull down our current death-rate to 15 in the 1000, perhaps to 12, and even to 10." Bird derided him and begged the audience to accept these ideas as from one who "was given to ideals—who let ideals take the place of data." Events have shown that Richardson was not so very far wrong in this particular instance; but in many cases we fancy that Bird's estimate of him was not undeserved. Richardson went to school in Leicestershire, and about that time lost his mother, to whose early training and care he owed a debt which he never forgot. She was a Calvinist, and was attended in her last illness by a medical man of the same persuasion. On Mrs. Richardson expressing her belief that she was one of the elect the physician remarked "that he had known many who had closed their eyes in sight, as they believed, of a glorious Heaven and had opened them, as he believed, to their amazement in a very different place." That medical man was asked not to call again. There is an interesting account of a meeting with Disraeli in a dress which recalls the description of Jingle. They met on the platform of Syston station, and the station master remarked prophetically: "He's a wonderful young man is that; gets into and out of debt, writes stories, and I shouldn't wonder if some of you live to see him a Minister of the Crown." Twenty years after they met again in the street, and Disraeli at once recognised his face. After serving his apprenticeship to Mr. Hudson of Somerby, Richardson entered at Anderson's College, Glasgow, where his principal teachers were Burns, Knox the anatomist, and William Thomson. Here he saw the first operation performed in Scotland under an anæsthetic—namely, ether—a sight wonderful enough even now, though so common that no one thinks anything of it, but that to one accustomed to the pre-anæsthetic operations must have seemed miraculous. Of such Richardson says, "I rarely knew any person who had positively made up his or her mind to undergo the operation, shrink from it at the last moment from fear of pain, and I rarely if ever saw one shed tears during the infliction of the pain"; but he also says that when the pain began patients would insist upon the operator stopping, and while he continued said nothing but "Make haste, make haste." While in Glasgow Richardson nearly died from a form of fever then prevalent, apparently relapsing fever, and on his recovery answered an advertisement in THE LANCET and became assistant to Mr. Thomas Browne of Saffron Walden in Essex. After this he went as assistant to the brother of the Mr. Hudson to whom he had been apprenticed, and from there went to Mortlake as partner with Dr. Willis. This period was really the starting point of his life's work. Here he met the lady who became his wife; here he collected materials for the Fothergillian Prize Essay and formulated the first idea of the lethal chamber. In 1853 he came to London and worked at the subject of the blood and its coagulation, coming to the conclusion that this depended upon the evolution of ammonia—a view he afterwards modified, although he maintained to the end the soundness of the principle that coagulation depends upon the evaporation of a volatile spirit. This theory led him to use ammonia as a solvent for thrombi and cardiac fibrinous exudations, sometimes with success, and once, as he honestly records, with fatal result from pulmonary embolism. Perhaps Richardson's greatest work lay in his efforts to promote sanitation, and the outcome of his work was the delivery of the paper on Hygeia, the City of Health, read at the 1875 meeting of the Social Science Association at Brighton. This address, if somewhat Utopian in its ideas, gave an enormous impetus to schemes of sanitary reform. It was widely noticed at home and abroad, and was even made the foundation of a novel by Jules Verne. We have not space here to notice the many other investigations in which Richardson took part, but must refer our readers to the book itself. All his theories—though it must be allowed that they are sometimes visionary—bore the stamp of earnestness and of a full consciousness like that of Newton that there were an infinity of things of which he was ignorant. He was deeply interested in the mystery of life and impressed with the expression, "God is light," as being some sort of explanation. "Truth," said Plato long ago, "is the body of God, and light is His shadow." "There are other powers," said Richardson (besides light and heat), "spiritual essences, according to our limited appreciation, but they are as mighty as subtle, and the breath of life is one of them."

We would suggest to the publishers that in the next edition an index might be supplied with advantage.

A Text-book of Comparative Anatomy. By ARNOLD LANG. Translated by HENRY M. BERNARD and MATILDA BERNARD. Part II. London: Macmillan & Co. Price 17*s*.

THE first part of this work appeared in 1891 and contained an account of the Protozoa, Cœlenterata, Platodes, Vermes, and Arthropoda. The present part deals with the Mollusca, Echinodermata, and Enteropneusta, and thus brings the description of the Invertebrata to an end. In its general plan the present part resembles in almost every respect that of its predecessor, and we are happy to be able to express as warm an appreciation of the labours of author and translators as we did on the last occasion. The work commences with a systematic review of the mollusca, followed by a hypothetical description of a primitive mollusc. Next, the outer organisation of typical forms of the chief groups are compared one with another and also with the above-mentioned primitive mollusc. The various systems are then considered in the following order: integument, shell, mantle cavity, respiratory organs, head, foot, musculature, and nervous system. Here there is a pause for a most interesting discussion on the causes of asymmetry in the gastropoda. Then the rest of the systems are dealt with, the sensory organs, alimentary canal, circulatory system, body cavity, nephridia and genital organs. After the devotion of a few pages to the subject of parasitic and attached gastropoda, the ontogeny of the mollusca is dealt with, Chiton, Dondersia, Paludina, Dentalium, Teredo, Cyclas, Anodonta, and Sepia being taken as types. The phylogeny of the molluscan phylum is next briefly considered, the author favouring a turbellarian ancestry for it, and the article is brought to a close by a review of the most

Hosted by Google

important literature of the mollusca carefully arranged under various heads.

This review of the treatment of the mollusca will serve to show the reader the scope of the work, since the echinodermata and enteropneusta are handled in a similar manner. The illustrations are copious, well executed, and carefully chosen, but we regret to see in some places the false economy of numbering the different parts and then telling the reader that the numbers are the same as in some former picture. In this way two or three illustrations have sometimes to be searched before a difficulty is cleared up, and when this happens often the whole thread of the subject may be lost. In the present instance, however, the fault does not occur very often, and we are the less disposed to lay stress on it since the descriptions in the text are so clear that a glance at the illustrations usually suffices.

The Natural and Artificial Methods of Feeding Infants and Young Children. By EDMUND CAUTLEY, M.D. Cantab. London: J. and A. Churchill. 1897.

WE entirely agree with the remarks with which the author of this useful little work introduces the subject to notice. He rightly points to the regrettable infantile mortality from gastro-intestinal affections, and points out how largely preventable such mortality would be if only more intelligence were brought to bear on the conditions of healthy feeding. He is to be commended for his endeavour to place the subject on a rational and scientific basis, and it is to be hoped that he will not have written in vain, and that more attention will be paid in the training of medical men in the important principles which he here so amply illustrates. We do not think that Dr. Cautley needed to apologise for inflicting on the medical reader a book of this class, for we feel sure that if its contents are thoroughly mastered [the practitioner will be much assisted in his methods of treating the commonest and most troublesome of infantile derangements. The book is carefully planned, so as to take the reader step by step through the critical periods of infancy, when so much depends upon correct management of diet. The condition of the mother, the management of lactation, the composition and changes in human milk, the composition of cow's milk, its sterilisation, &c., are discussed with detail and an abundant use of the knowledge gained by physiological chemistry. A very useful chapter is that devoted to Proprietary Foods, the use of which is often so indiscriminate. The diet after weaning, with regard to which further advice is given, is of quite as much importance as that of an earlier period of life. Chapters are also assigned to the Feeding of Premature Infants and to the Growth of Infants and Children, whilst appendices contain instructions for the preparation of foods and directions suitable for mothers of hospital out-patients. There can be no question that a book of this class was needed, and we do not think that the subject could be more satisfactorily treated.

The Bacteria of the Sputa and Cryptogamic Flora of the Mouth. By FILANDRO VICENTINI, M.D. Translated by Rev. E. J. STUTTER and Professor SAIEGHI. London: Baillière, Tindall, and Cox. 1897. Pp. 239. Price 7*s.* 6*d.*

THESE memoirs are translated from the "Atti della R. Accademia Medico-Chirurgica" of Naples. Dr. Vicentini has bestowed a large amount of time and labour upon the microscopic observation of the micro-organisms of the mouth and sputa. His studies have resulted in views or suppositions which are more or less directly at variance with the accepted facts of bacteriology and with the opinions of competent observers all over the world. If he were able to adduce any satisfactory evidence in support of his contentions, and if the methods he seems to have employed in his studies were sufficient by themselves to form an adequate basis for generalisation, no complaint could be made; but this is far from being the case. Dr. Vicentini appears to regard the methods of cultivation and experiment with distrust and has confined his attention to morphological observation alone, using very high powers of the microscope. As a result he is disposed to regard the tubercle bacillus, the gonococcus, and the diplococcus pneumoniæ as varieties or phases in the life history of one single organism—leptothrix buccalis, or, as he prefers to term it, leptothrix racemosa. We should add that these suggestions are made with the greatest modesty and diffidence. There is much to be said in favour of the pleomorphism of many bacteria, but such sweeping views as those here suggested naturally demand proof of the most rigorous description, and this is, in our opinion, not forthcoming.

In the first memoir the author details his microscopic researches into the sputum of whooping-cough, describing the presence therein of large quantities of "myelin," amounting sometimes to several grammes in twenty-four hours, and this he conjectures to be derived from the medullated nerve fibres of the air passages. This view of the pathology of whooping-cough would stand a better chance of acceptance if it were shown that there were enough nerve fibres there to furnish this continuous excretion and if proof were brought forward that the substance in question was actually myelin. The bulk of the book is devoted to morphological observations on the flora of the mouth and sputa. The observations are minute and detailed and they are illustrated by excellent coloured plates. They would constitute a valuable addition to our knowledge of the life-history of leptothrix could we have any confidence that they all really referred to one species. The conclusions, however, to which Dr. Vicentini is ultimately led will, we fear, only impress upon the reader the fallibility of even the highest powers of the microscope uncontrolled by other methods of bacteriological research. Professor Miller of Berlin, who writes a preface to the present work, is careful to dissociate himself from any participation in the author's views. The translation, though readable, is often obscure, and it abounds in technical inaccuracies.

A Pictorial Atlas of Skin Diseases from Models in the Museum of the Saint Louis Hospital, Paris. London: The Rebman Publishing Company. Price 10*s.* 6*d.*

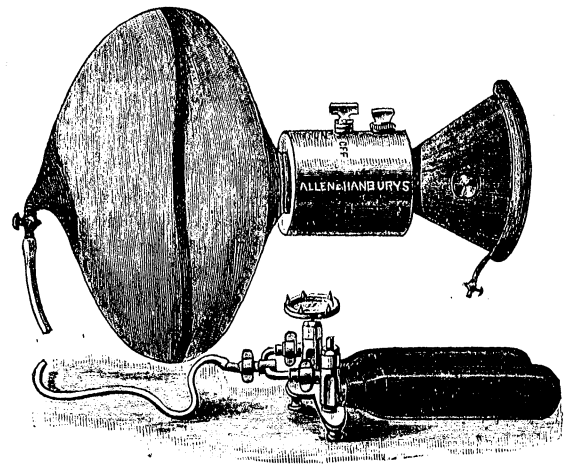
WE have before us Part VII. of this interesting publication. Plate 25 shows an ulcerating eruption on the back, which on Brocq's authority is labelled Bromide Eruption. The patient, however, was a syphilophobe and had been taking iodide as well as bromide of potassium, and the large pus-containing bullæ are rather more suggestive of iodide than bromide. Plate 26 is called Hypertrophic Papular Syphilide situated on the upper part of the chest. Jacquet calls them vegeto-papulo-erosive lesions identical with hypertrophic mucous patches, or condylomata of moist regions of the skin. He suggests that their presence in such an unusual position and of so large a size is due to the neglect and squalor of the patient. Plate 27 represents a lupoid syphilide and Plate 28 has two figures—a gangrenous tubercular syphilide and a gangrenous gumma. The various lesions are faithfully reproduced and continue an interesting series of representations.

Ligaments: their Nature and Morphology. By J. BLAND SUTTON, F.R.C.S. Eng. London: H. K. Lewis. 1897. Price 4*s.* 6*d.*

WE are pleased to welcome a revised edition of this admirable little work, which was first published ten years

Hosted by Google

ago. It has undergone some slight re-arrangement and some alterations in the author's views have been made, but in the main it follows the lines of the former edition. The formation of ligaments by the metamorphosis, regression, and migration of muscles, and by the degeneration of bony and cartilaginous tissues, is most clearly and interestingly shown. The ligaments of the extremities, pectoral and elvic girdles, larynx, and vertebral column are considered in order with regard to their morphology, and the student will be surprised to find how interesting the author has made the subject. It is a very valuable contribution to philosophic anatomy and one of the best scientific works that has appeared in recent years.



JOURNALS AND REVIEWS.

Zhurnal Meditzinskoi Chimii i Pharmatzii (Journal of Medical Chemistry and Pharmacy). December, 1896.—This Russian journal is published and edited by M. Poehl, a chemist of reputation in St. Petersburg. Much of the present number is taken up by articles by the editor and other observers on the nature and action of a proprietary preparation known as "Spermin-Poehl." As its name implies, this is an animal extract prepared much in the same way as that originally described by Brown-Séquard. "Opoovariinum-Poehl" is an analogous preparation of ovarian substance, which is said to be of use in relieving morbid symptoms appearing at the climacteric period. Articles on this use of ovarian extracts by Professor Landau and Dr. Mainzer of Berlin, which have appeared in the German journals, are here inserted in full. Over fifty pages of the present number are devoted to the answers received from various sources to a list of questions previously issued by the editor dealing with the clinical effects of his preparation of spermin. The questions and answers are printed in the four languages, Russian, French, German, and English. The individual replies, of which M. Poehl appears to have received a large number, are condensed into brief sentences, all of a highly laudatory character. The method savours too much of the advertising tactics pursued by the proprietors of quack medicines to be commended. It is probable, also, that some negative or even adverse replies were received, and these should have been published side by side with the favourable ones, if the preparation in question is to be regarded as other recognised therapeutic agents and not as a mere proprietary remedy.

New Inventions.

IMPROVED ETHER INHALER.

MANY of the ether inhalers in present use have a very constricted air-way, and, in fact, a feeling of oppression arises when breathing through them even before the ether is turned on. As a result of such mechanical obstruction cyanosis, a large pupil, and laboured breathing are witnessed during the subsequent anæsthesia. I have long been desirous of providing an ether inhaler with a really free breathing channel, because I believed that if this asphyxial factor were abolished the induction of anæsthesia would be more pleasant to the patient and the resulting condition during operation would also favour the diminution of after-effects. The accompanying illustration shows a metal expansion chamber which I have designed to meet the requirement. Its weight is the same as that of a small Clover's inhaler, but it contains six ounces of ether, and does not therefore require filling during an hour's operation. It requires no water-jacket, because the heat absorbed and rendered latent by the evaporation of ether is not removed from the liquid in the reservoir, but from the patient's breath alone. It consists of a cylindrical reservoir for ether which surrounds a breathing channel two inches in diameter; a small metal shaft runs vertically from the tap above, through the breathing channel, communicating below with the ether chamber; a hollow metal plug fits this shaft, and through a pinhole in the axis of the breathing channel a fine stream of ether is directed upon the sponge through which the patient breathes. The warmth supplied by the administrator's hand holding the cylinder is enough to cause a rise of temperature within it of from 10° to 15° C., which produces a force of expansion and vapour tension in the chamber equal to a pressure of 27·24 c m. of mercury, and this on the principle of Dalton's law, is sufficient to propel a stream of ether from the pinhole orifice until the cylinder is empty. The type of anæsthesia produced by the inhaler in more than seventy cases for which it has been used fulfils my expectations very perfectly. It presents a smaller pupil than usual and a very bright colour; the breathing, though deep, is remarkably free from stertor, and the induction even

with ether alone is quiet and smooth. The cylinder can be filled and carried about in that condition without any leakage; there is no smell of ether at all before beginning the inhalation, and as the patient's breath does not pass into the reservoir ether left in it is absolutely uncontaminated. The administration of gas and ether is thus conducted. 1. Fill the cylinder with six ounces of ether through the stoppered apperture and screw this down tightly. 2. Turn on the ether tap to see that it works; then pack the sponge loosely into the breathing channel around the little trumpet orifice and especially below it. 3. Attach the bag with tubing from the gas bottle; then, after emptying the bag of air, a little gas is allowed to run into it and the face-piece is accurately applied whilst (if lying recumbent) the patient's head is turned towards the side. 4. After five inspirations turn on the ether tap, then off again, and during succeeding breaths the tap is opened and closed until, the sponge being wet, signs of ether narcosis supervene.

Messrs. Allen and Hanburys, of Wigmore-street, are the makers. To them I am indebted for much personal courtesy and the sparing of no effort in the production of every detail with accuracy and excellent workmanship.

H. BELLAMY GARDNER, M.R.C.S. Eng., L.R.C.P. Lond.
Welbeck-street, Cavendish-square, W.

MERTHYR TYDVIL GENERAL HOSPITAL.—The new accident ward added to the western side of the Merthyr Tydvil General Hospital was formally opened by Sir W. T. Lewis on Feb. 24th. The high constable of Merthyr, at the ceremony, stated that the Queen had been pleased to allow the ward to be called the "Diamond Jubilee Ward." It was stated that Sir W. T. Lewis had been instrumental in getting two donations of £1000 each from the Marquis of Bute, and had himself contributed £750 towards the building of the hospital, besides giving £1000 towards this new ward. It was announced that £1170 had been subscribed at the luncheon that followed, which included £400 from Sir W. T. Lewis and members of his family and £100 from the medical staff of the hospital.

THE LANCET.

LONDON: SATURDAY, MARCH 20, 1897.

THE success of the PRINCE OF WALES'S Hospital Fund for London in commemoration of HER MAJESTY'S long and beneficent reign is a matter of deep interest to ourselves and to the public. To ourselves we say, for it represents a scheme which we have long and specially advocated, and which we were fortunate enough to anticipate and urge as one particularly fit to be associated with an epoch in which medicine and surgery have advanced by strides and during which their methods have increased in gentleness as they have in efficiency. But the public is equally concerned in the success of the PRINCE'S Fund. English philanthropy is best illustrated in the voluntary hospitals. Englishmen do not like to be taxed; but they tax themselves for the support of these institutions, which will bear a favourable comparison with any hospitals of the world. It is true, as the PRINCE has well pointed out, that this self-taxation is a very limited matter. The hospitals and other charities are, or at any rate have been, supported by a mere handful of people. Whether we take London or the provinces, it is apparent that a large majority of the people, even well-to-do people, has been content to see the hospitals supported—or to see them starved—without dipping into its own pockets on their behalf. Not the least service done by His Royal Highness in this present year is to have brought out this fact. He has made it clear that, either from inadvertence or from want of sympathy—with characteristic good nature he adopts the former alternative—the ordinary well-to-do Englishman has acted as if the hospitals were fed from some secret or Divine source, and left somebody else to do the work of "the good Samaritan" while he "passed by on the other side." Henceforth there will be no excuse for this evasion of the plainest duty entailed upon comfortable and healthy people, to provide for those necessitous inmates of hospitals who are neither comfortable nor healthy. We heartily adopt the PRINCE'S theory, that the starvation of hospitals in the undoubtedly wealthy community of the metropolis has risen from "want of thought" and not "from want of heart," and henceforth we hope to see a rivalry in enlightened and self-denying liberality. The time is short. We do not believe in the indefinite prolongation of exceptional emotions. We are all enjoying the consciousness of the pleasure of living in the Victorian Era, in which the Throne has seemed to be the source and seat of every virtue that can sweeten and elevate the life of the nation. There is but one wish, and that is for its continuance. Let us none the less make much of it and of the thankfulness which it generates. It will be no slight monument of our gratitude if we can make our hospital treasurers take new heart of hope and fill their empty beds with sufferers that languish in ill-adapted rooms—of which, let it be remembered, there is a terrible tale in our very midst; for have we not been told of recent years of the disgraceful number of one- and two-roomed tenements, of people living within a stone's-throw of wealth and luxury under the vilest conditions, in numbers altogether equalling the population of a large provincial town?

We may be told that we are forgetting the abuse of hospitals, and the fact that institutions which were founded for, and have been hitherto placed at the service of, the poor "without money and without price" are now being used on commercial principles and bartered for petty sums that degrade charity and medical service at one stroke. We do not plead guilty to the charge of forgetfulness. Our columns from week to week show how (faithfully and vigilantly, we trust) we labour to bring back hospitals to their true use and to expose unflinchingly all abuses. Our readers will give us full credit for this. We shall not be content till we have eliminated from hospitals all those whose homes and whose circumstances admit of treatment and their recovery at home, and till we have reduced the out-patient department to proportions consistent with the advantage of patients on the one hand and the just interests of medical practitioners on the other. But there is a time for everything—a time for collecting money for an object, and a time for insisting on guarantees that the object shall be defined and distinct. We do not share Mr. BURDETT'S views, that the Hospital Sunday Fund and, by inference, the PRINCE'S Fund are collecting bodies, having at present but little responsibility for the use of what they collect. With every respect for Mr. BURDETT and his great interest in hospitals, we regard this as an ill-advised doctrine, which threatens seriously to injure such funds and the institutions the benefit of which they contemplate. We venture to believe that the council of the PRINCE'S Fund, not excluding His Royal Highness himself, hold no such narrow view of the duties incumbent on them; and in this belief we shall continue to wish them every success in their efforts. We are quite willing to assume their agreement with us that hospitals are for the poor, and that it is contrary to the interests of the poor, of the public, and of medical education to convert them into cheap dispensaries, alienating the working classes and classes better off from the private practitioners to whom they must always be most indebted for medical guidance throughout life.

The weak part of the voluntary hospital system is the uncertainty and precariousness of its income, and its reliance on small patrons, who are apt to think of personal advantage or the advantage of their dependents rather than of the true uses of hospitals and the superior claims of the poor. The best cure for this is the liberality of the liberal, of those who contribute to hospitals for the sake of the poor, and without the intention or the wish of personal advantage. For this reason, as well as for the honour of our illustrious QUEEN, we rejoice in the success of the PRINCE'S Fund. We should like to see every established hospital of repute made independent enough to lay down rules for its own administration and to adhere to them when laid down—a wish in no wise inconsistent with a Central Board so constituted as to

Hosted by Google

command the respect of individual institutions and to facilitate their beneficial and harmonious coöperation.

THE latest reports from India show that very elaborate and stringent arrangements have been made throughout that country for the application of the powers conferred by the Epidemic Diseases Act for limiting or preventing the spread of bubonic plague. In addition to all that has been already done in Bombay, and to the large augmentation of the medical strength that has been made for duty under the Bombay authorities during the continuance of the epidemic, an Executive Committee has been organised and vested with power to enforce and carry out the measures that have been devised for combating the scourge. The disease seems to be mainly confined to the city and to Bombay Presidency and Sind; it has now been present for some months in the former place, to which it has manifested a chronic sort of adhesiveness which is suggestive of its dependence upon local conditions for its incidence and persistence. In the extent or rapidity of its spread in India the disease has not been at all comparable to what has occurred in these respects in epidemics of cholera in that country. But the alarm that has been created in Europe by the presence of plague in India has, as we know, been great, and has led to the imposition of restrictive measures with very seriously paralysing effect on the commerce of that country. The impression left upon the mind from a broad survey and study of the facts making up the recent medical history of plague in the East is that it is largely a preventable disease, and to a far greater extent capable of being controlled and treated than might be inferred from the alarming descriptions of it in past history.

We cannot be surprised that, with such additional experience as France and other Continental nations could adduce, the very name of the disease should give rise to grave alarm; but people are nowadays disposed to take calmer and more moderate views, and that this is so is attributable to the fact that we now know more about epidemic diseases and the way of combating them. Notwithstanding much that still remains to be cleared up in regard to plague, the fact remains that we have learned more about its nature, causes, and treatment within the last few years than we ever knew before. We have ascertained from a bacteriological study of it that it depends upon an inoculable micro-organism; that it not only affects man, but the lower animals (rodents especially), and probably some insects (flies, for example); that it is, on the whole, a less infectious disease than had been supposed; that local conditions and an insanitary environment are necessary factors in furnishing a fitting soil for its spread and development; that its progress as an epidemic—as compared with cholera, for example—is relatively slow; and that there is every reason to hope that, as a result of our experimental methods of research, a relative immunity from attack may be conferred by prophylactic inoculation, and, when actually attacked, that a curative remedy is not beyond our reach if we continue to prosecute our researches on the lines which Dr. YERSIN and Professor HAFFKINE have indicated. While Dr YERSIN has prepared a serum which he regards as a curative agent in cases of plague, Professor HAFFKINE has succeeded in manufacturing a vaccine or protective lymph which will, he thinks, to a certain extent fortify the system against an attack of bubonic fever. Both the alleged curative and preventive plans of treatment are founded upon the results of the experimental methods of inquiry, and are the outcome of the modern science of bacteriological investigation. Our readers are already acquainted with the work performed by Dr. YERSIN in China in this direction, and with the belief which he entertained that he had succeeded in preparing a curative agent for the treatment of plague. He has now returned to Bombay, and entered upon his work there on the 6th instant. The effect of his remedy on plague patients only ill for a day or two is reported to be, according to the reply of the Earl of ONSLOW in the House of Lords on the 11th inst. to a question by Lord REAY, "surprisingly good," while more advanced cases are not so much benefited. Professor HAFFKINE has communicated the results of the scientific experiments instituted by him to the Standing Committee in Bombay. By means of culture experiments in different media he has been enabled to cultivate the plague bacillus in abundant and concentrated quantities, and has tested their virulence on large rodents. From these experiments as a starting-point he subsequently prepared other cultures which were deprived of their fatal properties, until he reached a harmless culture which proved protective against a dose of the living virus that would be speedily fatal to non-protected animals. With this he inoculated himself and subsequently some members of the medical profession. Lord ONSLOW now tells us that up to and including March 7th 2341 persons have been inoculated, of whom only two (in addition to two previously mentioned) have been attacked by plague; both attacks occurred within five days of inoculation, and both sufferers are alive. People are coming forward more freely to be inoculated, and the practice is extending. The Government of Bombay are preparing an organisation for the extension of depôts for purposes of inoculation and for instructing medical officers in the process. Steps are also being taken by the Governor for popularising prophylactic inoculation and for increasing the amount of lymph that can be produced. The Secretary of State will receive information weekly of the extent to which the practice is resorted to, with reports as to its efficacy. The results of a more extended trial Lord ONSLOW has offered to communicate to the House of Lords.

It would be obviously premature to pronounce any opinion at present as to the final outcome of these methods of dealing with the disease. We can only await the results with extreme interest. About the zeal and self-sacrifice of those engaged in prosecuting these investigations there cannot, in the meantime, be two opinions; and we think that both the Government of India and the Secretary of State for India are also deserving of great praise for the way in which they have facilitated and seconded the efforts of scientific medicine in these directions. It has been said that the Bombay authorities were to blame for not having adopted from the first all the sanitary and precautionary measures that are now being carried out, but it is proverbially not easy to be

Hosted by Google

wise in time, and it is a very serious thing for any Government to incur the responsibility of officially declaring the presence of plague in a city, with its attendant consequences to a community of mixed races and religions and to trade and commerce, until thoroughly assured of the fact. We are bound in fairness to recognise the difficulties of such a situation, and we may add that probably in no country in the world would the efforts to limit the spread of contagion and to combat and deal with difficulties have been more thoroughly undertaken and discharged than seems to have been the case in India, not only in regard to the pestilence of which we have been writing, but also in connexion with the great famine which is prevailing there at the present time.

PROFESSOR PAGLIANI of Turin, who holds the chair of Public Hygiene in the University (a department in which he has been one of the most trusted officers under Government), has just been allaying the panic of his compatriots in view of the plague in the Bombay Presidency—panic which, among other disastrous results, is hurting Italy on a side where she has every need of being spared—namely, her commerce. She has, he says, been following the example of Marseilles, which asked and obtained from the French Government the "boycotting" of every vessel hailing from the infected Indian ports. Palermo and Naples, in imitation of their French sister, have imposed on the Società di Navigazione the regulation that no ship of similar origin shall enter their harbours, thereby, he says, reviving the measures which proved so mischievous to commerce in the cholera epidemic of 1884-86 and also reviving the anarchical spirit of the communes in sanitary administration, when, as in those years, each commune acted for itself, to the prejudice of sound hygiene and to the damage of every interest, moral and material. In 1887 that spirit was, with infinite trouble, exorcised, but now it seems we are to have it rehabilitated. He hopes that other harbour towns—Genoa, for instance—will put their southern sisters to shame by ignoring such irrational means of defence. Meanwhile, he asks, "How is our commerce affected by the procedure of Palermo and Naples?" Italy's "movimento marittimo" (maritime intercourse) with the Indies constitutes more than three-fifths of such "movimento" as a whole, and her Government is in annual receipt of three and a half million lire collected as harbour dues from the Indian traffic alone, five million being the sum total of such receipts from all sea-faring traffic put together. From Palermo and Naples she is to forfeit these receipts, and from whatever other harbour towns follow suit! And what basis in science or in common sense exists for such panic? None whatever. Of course, he does not deny the danger of plague-stricken vessels with patients on board entering a largely frequented seaport. Ample means for obviating that risk are in working. But it is quite another matter in the case of vessels which, after a very long voyage, during which they are safeguarded in every way, approach the harbours. In such cases the period of incubation is long past; and as for soiled effects which these ships may carry there are means at every harbour of disinfecting them forthwith. It is therefore only from certain classes of goods that the suspicion of transmitted infection may arise. And here he gives the weight of his authority and experience to the declaration that "no proof exists of an epidemic of 'pestis bubonica' having been propagated by merchandise or by articles of private or domestic use."—except in the case of the latter when they have passed from the person of a patient without being disinfected. "Neither woollens," he proceeds, "nor skins, nor fleeces of any kind have ever transmitted an epidemic." Adducing epidemiological observations to prove this, he adds that from the bacteriological point of view the bacillus of plague has, so far as science is aware, such biological properties that even in the improbable case of a patient having directly or indirectly infected goods prepared for exportation it very quickly loses all infective activity in the transport of the goods themselves. A doubt has been raised as to whether the hides of animals which have died during the epidemic of plague may not convey the infection to a distance. But the apprehended risk vanishes with Dr. LOWSON'S demonstration, and still more after the investigations lately completed by Professor PAGLIANI himself and his colleague, Professor GIACOSA. Such hides in the dried state, even supposing that the "pestis bubonica" of man could declare itself in cattle, are, they showed, quite incapable of preserving alive the bacilli they, *ex hypothesi*, may have contained; the treatment they have undergone has made such life impossible. "Neither epidemiological reasons nor such as the laboratory can bring to the test can justify the prevailing dread of goods proceeding from plague-stricken localities—a dread fraught with damage to our commerce, to our national economy, and to our industrial classes.....It is difficult," he concludes, "to run counter to a popular current inspired by the gust of fear; it is far easier to win applause when one favours the prejudices of the crowd; but it is the duty of hygienist and philanthropist alike to defend in every case, not only the health of the masses, but also their sound judgment and the sources of their sustenance."

Annotations.

"Ne quid nimis."

THE TUNG WA HOSPITAL, HONG-KONG.

WE have received the blue-book dealing with the report of the Commission appointed by His Excellency Sir William Robinson to inquire into the working and organisation of the Tung Wa Hospital, Hong-Kong—a Commission which, to our minds, reveals the existence of a most serious state of matters in a British colony. We have read the report very carefully, and, although we may be thought presumptuous in differing upon the evidence therein set forth from those Commissioners who were on the spot and heard that evidence given, we cannot but think that the majority report, signed by three out of five Commissioners, is too optimistic. Even these gentlemen recommend a great many improvements as being desirable, among them the daily inspection of the hospital once, or more than once, by an officer of the sanitary board, the water carriage of excreta, regulations against overcrowding,

Hosted by Google

regulations for the cleansing of bedding, and, finally, more stringent laws for the prevention of infection. The Hon. C. P. Chater, while agreeing with the majority report, wishes to add that as to the work of the hospital as an institution for healing the state of matters is far from satisfactory. "We find doctors who have never been to any medical college ..... whose only test of knowledge is to be able to write a thesis to be approved of by their colleagues in the hospital, who permit men to die because they cannot or will not perform a simple operation. ..... We find, too, the horrible custom of herding the most foully diseased with their less afflicted fellow patients with the natural results, and, in fact, almost every law of hygiene slighted." The Hon. T. H. Whitehead has a long memorandum of his own opinions on the management of the hospital and sundry recommendations, of which the most important are—(1) the appointment of a resident European sanitary inspector; and (2) the gradual appointment of Chinese medical officers *trained in Western methods of medicine*. (The italics are ours.) All the Commissioners acknowledge that the sanitary state of the hospital has improved since 1894, but very much remains to be done. Let us quote the evidence of the principal medical officer of the Army Medical Staff in the colony, Surgeon-Colonel Evatt, taken on July 2nd, 1896. The exact dates of his visits to the hospital are not given, but as he only arrived in the colony in May they must have been between that time and the date on which he gave his evidence. "The number of commodes was most marked. There was a perfect epidemic of commodes, and there were patients suffering from diarrhœa in the same wards with other patients suffering from open wounds. ..... That day we visited the hospital some of the commodes were in a most dreadful state. The stench was enough to make anybody ill who was well, and it must have been bad for the sick inmates." Now, we consider that, to quote the words of the Hon. C. P. Chater, "such a state of things should not exist in a British colony, and in an institution partly supported by the Government of that colony." The hospital, of course, was built for, and partly by, the Chinese, so it would be ridiculous to try to administer it in a purely Western fashion, for most Western ideas are entirely unfitted for Orientals; but with regard to sanitary matters they concern the health of the whole community and *must* be set right. As regards Chinese methods of treatment and nursing they will have at present to remain as they are until a supply of native medical men are trained in Western medicine, which Orientals can appreciate, as witness the Japanese and some of the races of India. Oriental filth is a matter which, to use a trite journalistic phrase, must be seen to be appreciated, and we can only hope, nay, more, we may say demand, in the name of the medical profession, that the Colonial Government will take steps—if, indeed, it has not already done so—to remedy the grosser evils pointed out in this report.

THE WORK OF THE HOSPITAL SATURDAY FUND.

THE annual meeting of this Fund was held on March 3rd, when the chairman, Mr. Reginald B. D. Acland, delivered an address dealing with the work of 1896. With reference to the question of new premises he pointed out how entirely unsuitable and cramped the present offices of the Fund were, and mentioned that it had been decided to purchase some new premises in the Gray's-inn-road much more convenient than those in Farringdon-road as regards space and less expensive as regards rent. Passing on to details the chairman said that during the year 28,708 letters had been received and dealt with almost without complaint. The actual receipts for the year were £21,614 odd, and the percentage of expenses to receipts was 11·81. The Ambulance Committee, which has only been in existence thirteen months, has done good work and is now working in complete harmony with the St. John Ambulance Association. The Surgical Appliance Committee supplied 2782 appliances, such as spectacles, artificial teeth, legs, and arms, and spinal machines. With regard to cases sent to hospital the Fund is making a praiseworthy effort to sift their applicants before sending them to chest hospitals at least. "In response to applications for such letters 1101 forms of medical certificates were issued ..... of these applications 556 were never heard of again, and of the remainder which were returned only 313 were found suitable for chest hospitals ..... 20 were sent to general hospitals, and 212 to the metropolitan dispensaries." From this it would appear that more than half the applicants refused to submit themselves to a medical examination previously to going to the hospital. The chairman referred to the articles which have recently appeared in our columns upon hospital abuse, and remarked that the writer "seems to mean that a hospital is abused if the result of the patients going to the hospital is that they do not go to the general practitioner." He did not think that as a class the patients who attend our hospitals do so with the idea of avoiding payment to a professional man, but because they think they get better treatment than at home. The question, however, was exceedingly difficult, for there was no body of men who lived more self-sacrificing lives than general practitioners among the poor. We can assure Mr. Acland that there is abuse, and that very real, of the charity dispensed by hospitals, and we are glad to see that he remarked, in the course of his address, that "the time has come when associations like ours should do something to try and stem this ever-increasing stream of out-patients."

MEDICAL STUDENTS AND VACCINATION.

THE anti-vaccinationists, whatever their demerits, are by no means wanting in energy, and to the vigorous manner in which they appeal to the ignorant electorate must be attributed in no small degree the existence of distorted notions and erroneous ideas. It is obvious that if the mistaken views which so largely prevail are to be replaced by views more in accordance with the truth there is much to be done. The arguments of the opponents of vaccination are not difficult of refutation, but it is nevertheless absolutely essential that they should be carefully studied in order that fallacies, suppressions, and distortions with which they so frequently abound may be laid bare. It is therefore necessary, not only that the public should be educated by means of attractively written pamphlets in forcible and easily understood English, as well as by lectures, but that the medical men of the future should also be put in possession of all the facts, fallacies, and arguments. In this direction Dr. Theodore Acland has done excellent service at St. Thomas's Hospital Medical School. Not only has he given a series of lectures on the alleged injuries from vaccination, on which subject his experience in connexion with the Royal Commission on Vaccination entitles his opinion to be received with great weight, but at a recent meeting of the Medical and Physical Society he delivered an excellent address upon the subject of Compulsory Vaccination, in which he put before the members an eminently unbiased statement of the case, which should serve them in excellent stead in the future combats which are sure to fall to their lot. Dr. Acland had little hesitation in urging that if we wish to reduce small-pox to the smallest limits there is required practically universal vaccination and re-vaccination. Obviously, as we have recently pointed out in our columns, this is the only logical conclusion to be deduced from the report of the Commissioners and that of the dissentients, and it is much to be hoped that the staff at other medical schools will be able to follow Dr. Acland's

Hosted by Google

example and to put before the students the arguments for and against vaccination. The Epidemiological Society has recently done good work in answering, through the admirable paper of Dr. McVail, the report of the dissentients. It is, we believe, the intention of the society to publish this paper separately from the Transactions[1] and to send a copy of it to every Member of Parliament, together with the resolution recently passed by the society as to the necessity for vaccination and re-vaccination. We certainly trust this will be done, and that the House of Commons may at least have the opportunity of examining into some of the methods of attack and defence of the anti-vaccinationists.

THE HEALTH OF THE TSAR AND THE TSARITSA.

WE are informed upon excellent authority that there is no foundation for the alarming rumours regarding the health of the Emperor of Russia which have been industriously circulated during the last few months. His Majesty does not suffer from any cerebral symptoms, as has been alleged; he is out every morning as soon as it is light, and keeps himself in condition by running a verst (1160 yards, or about five furlongs), watch in hand, to see that he can do it in his average time. One of his amusements is said to be shooting from a bicycle, and he can bring down a crow even when he is going at a good speed. The recent illness of the Empress has also been exaggerated. It was not of the serious nature commonly supposed, but only an ailment incidental to pregnancy, and the accouchement is duly expected in April.

THE UNIVERSITY OF BORDEAUX.

THE inaugural ceremonies connected with the University of Bordeaux were this year celebrated with more than usual pomp and circumstance; but, unfortunately, the students were of opinion that as a body they had not been treated with due consideration in the matter of accommodation, and for a considerable time it seemed as though the orators would not be allowed to proceed with their discourses. At last, during a lull, the rector, M. Couat, began his speech, and being very popular soon commanded the attention of the unruly throng. In 1854 there were only five pupils in the faculties of science and letters, and the treasury of the institution was well-nigh empty; whereas at present, with a reserve of ten million francs, the number of students has risen to 2191, and there are no fewer than 101 professors to attend to their requirements. "As for the output of the University," exclaimed the orator, "I do not wish to weary you by a lengthy enumeration of titles, neither shall I wound individual modesty by quoting names. It is enough if I recall the fact that in all the domains of research, in the sciences both natural and moral, in pure mathematics as well as in philology, the professors of the various faculties of Bordeaux have by their numerous works contributed largely to the advancement of knowledge and to the glory of French literature." While the ceremony inside the building was in progress a very noisy demonstration took place in the street among the shut-out students, the disturbance being fomented by the mounted police, who sought to clear the ground by spurring their horses amidst the crowd. For some time a collision was imminent, but happily a commissary who was endowed with a modicum of sense appeared upon the scene and soon peace was restored. In order to manifest their approval of this gentleman's judicious action the merry students shouldered him in triumph and carried him off, but where they went to the reporter omits to state. So far the events occurred in the daytime, but the same night matters reached a crisis. At a gala performance in the Grand Theatre the students, to their disgust, found themselves "relegated to paradise," and having thus to "roost among the rafters" determined that the audience should be made aware of the fact. It was as though the barnyard denizens of the entire province had found their way into the building, so stupendous was the crowing and cackling. The demonstration, however, was not in reality a spiteful one, and eventually the entire theatrical programme was executed. Meanwhile, the young men who were unable to gain admission even to the "cock-loft" grew more and more excited, and ere long a veritable riot was in progress all round the theatre. The misguided youths strove to make their way in by force, only to be harshly repulsed by the police. Blows with the fist were freely interchanged, and in several instances sticks and bludgeons were used with effect. Eggs of an uncertain age and other similar missiles were not wanting, stones flew about, and the windows of neighbouring cafés were shattered. Finally, the mounted gendarmerie were ordered to charge, and after a brief struggle, during which wounds were liberally inflicted on both sides, the *émeute* ended at one o'clock in the morning. About a dozen of the riotous students spent the remainder of the night in the lock-up, where they were not allowed any food. This, however, was not considered a sufficient punishment, for several of them were condemned to eight days' imprisonment. It is to be hoped that this severe punishment will be a lesson to these Bordelais raiders and that in future if they think they have grievances that demand redress they will confine themselves to strictly constitutional methods.

"BLOOD ERYTHEMA."

MR. MARMADUKE SHEILD[1] proposes this name for a peculiar eruption, not previously described, produced by contact of arterial blood, of which he is himself the subject. On washing away the little crusts of dried blood which remain after operations a faint pink erythematous spot appears in the site of each, which darkens to a faint red, lasts about half an hour, and slowly disappears. The eruption is not attended with itching or inconvenience, and principally occurs on the backs of the forearms and on the forehead. He has also seen it upon the forearms of his assistants, though not so vividly, and twice on the skin round an amputation of the breast. It is remarkable that this peculiar phenomenon, of which surgeons themselves are the subjects, should not have attracted attention hitherto. Mr. Sheild has no doubt of its occurrence, as he has noticed it so frequently, and confirmation of his observations is forthcoming. At a recent meeting of the Dermatological Society of Great Britain and Ireland[2] Dr. Harrison of Clifton stated that having read Mr. Sheild's case he was led to inquire into that of a medical friend, who when sprinkled with arterial blood on any part of the body felt an irritation. After washing away the blood a pink stain remained, which lasted fifteen minutes or longer. Another speaker mentioned the case of a medical man who was neurotic and asthmatical, and to whom the smell of blood was loathsome. After attending a case of post-partum hæmorrhage an erythematous rash was to be seen on the arm, where the blood had been projected, some hours after careful washing. There was also some irritation of the skin. What is the explanation of this curiously produced erythema? Mr. Sheild thinks, as it is not constant, it must depend on some peculiarity of the patient's blood. We cannot agree with this. The peculiarity seems rather to be in the subject of the eruption. All the facts support this view. He does not associate it with any special condition of the patient; and the subject of Dr. Harrison's case distinctly states that any arterial blood would produce

[1] An abstract of Dr. McVail's paper will be found on page 809.

[1] British Journal of Dermatology, November, 1896.
[2] Ibid., January, 1897.

Hosted by Google

the effect. We consider that it is an example of idiosyncrasy, which accounts for its great rarity. It is perfectly analogous to the eruptions and other symptoms produced in certain individuals by small doses of some common remedy or some ordinary article of diet. There is the difference that the eruption in question is produced by local irritation, and not by internal administration. This is no objection, however, to our view. If considered so it can be met by citing similar cases of eruptions so produced. An ordinary linseed-meal poultice or the application of yelk of egg (Ord) will cause urticaria in some persons. These agents would certainly produce as little effect on ordinary skins as the contact of blood. Again, asthma in some forms is an example of idiosyncrasy; for instance, that produced by the odour of one of the domestic animals. Now it is curious that the subjects of the two latter cases of blood erythema were very susceptible to the odour of blood, and one is described as neurotic and asthmatical. The fascinating and important subject of idiosyncrasy has received but little attention. There is little more than a scanty record of cases, and scarcely an attempt at investigation of the subject as a whole. The phenomena are regarded as inexplicable and as standing quite apart from all others. This attitude is not scientific. Cases of idiosyncrasy, like those of rare diseases, should be regarded, in accordance with Mr. Jonathan Hutchinson, as extreme examples of variations which are but ordinary. Thus the key to explain why that which is harmless to almost all should be toxic to a few is the admitted constant variation in the action of all drugs. We suggest that blood, owing perhaps to the volatile oil which gives the odour, is an irritant too weak to affect an ordinary person. In a small minority some erythema—so trivial and fugitive as to escape observation—may occur, which becomes distinct in a few extreme cases of special susceptibility. Thus far we may theorise on idiosyncrasy. To go further more facts in the form of carefully recorded cases are required. If this view is correct, it will be found that, as in the case of rare diseases, these cases are not so uncommon as we might suppose; and that, in addition to well-marked forms, there is a greater number ill defined which have escaped observation for want of the attention which only follows the discovery of the former.

TINNED SALMON.

OUR contemporary the *Globe* published a letter recently from a correspondent who signs his name and vouches for the following. Last summer he was at a "cannery" at Steveston, on the Frazer River, and "saw fish received from the fishermen, in large and small lots, varying generally from thirty to five fish, and kept piled upon one another just as thrown in from the boats for several days, until something like two or three thousand fish were on hand, before cleaning and canning, so as to save the expense of steam, &c. The thermometer is rarely below 70° and often 90° F. in the shade during the greater part of the canning season, so that you may imagine the condition of the fish first received, which would be underneath the later lots at the time of putting into the cans. The Chinamen who gut the fish use the keenest knives, constantly ground and sharpened, but are often unable to make a clean cut or to prevent the flesh tearing away, owing to its rotten state. But however bad the fish is, it is canned. This is the usual state of things, but I have seen at the busiest times so many as 15,000 or 16,000 fish piled up three or four feet high, and the stench arising abominable." He admits that the fish after being canned are exposed to a high temperature for two hours before the tins are finally sealed, but he also says that previously to being put in the tins they are "cleaned" by being washed in the river, which is a mass of filth from floating offal. Now we have no doubt that the heat of cooking destroys all bacilli, and perhaps also their spores, but putrid fish, even under these conditions, is not a fit food for any human being. Even if micro-organisms and their spores are destroyed there may very probably remain the putrefactive alkaloidal bodies, which act as poisons of the most virulent kind. The writer of the letter is prepared to give the name of the cannery in question, and advises that the output when it arrives, as it is expected to do, at Liverpool, should be seized and destroyed. He also mentions that there were several cases of enteric fever among the employés last summer with at least two deaths. If what the writer says is true steps should be taken to examine the consignment of the factory in question. In the meantime his statements have been categorically contradicted.

THE BENIN MASSACRE.

CAPTAIN BOISRAGON, one of the two white survivors of the Benin massacre, has returned to England, and in the course of a statement (published in the *Times* on the 17th inst.) which he made to Reuter's Liverpool agent thus bears testimony to the heroism of Dr. Elliott, who was killed in the attack: "While we were carrying Major Crawford, Dr. Elliott, who was bleeding from a wound in the head, kept on charging into the bush, trying to prevent the Benin men from shooting at us, for we could only go very slowly. He most undoubtedly kept them from coming close up to us and saved us from being hit several times." Captain Boisragon also acknowledges the services rendered to the survivors by Dr. D'Arcy Irvine when they reached New Benin. We also note in the *Times* of the 16th inst. a Reuter's telegram from Lagos stating that Mr. Allman, Principal Medical Officer H.M.S. Niger Coast Protectorate, is, with the Consul-General, actively engaged in improving the sanitation of Benin city.

A CASE OF EXTENSIVE SKIN-GRAFTING.

AT a recent meeting of the Philadelphia County Medical Society Dr. T. S. K. Morton showed a man, twenty-six years of age, whose left leg had been scalded with boiling water, the consequence being that the entire thickness of the skin sloughed from seven inches above the patella to the malleoli at the ankle, and only a few small islets of skin on the crest of the tibia were preserved. Some eight weeks after the accident Dr. Morton commenced the application of skin-grafts after the manner of Thiersch. The granulations were sterilised as much as possible by spraying with hydrogen dioxide diluted one-half with normal salt solution (0·6 per cent. common salt in water), and were subsequently enveloped in gutta-percha tissue. When suppuration had been largely controlled by this treatment a surface about ten inches long and two inches wide was scraped with a curette. Bleeding was free, but was easily controlled by the binding on of sponges whilst the grafts were being cut. The skin of the opposite thigh having been shaved, sterilised, and oiled, strips were cut from its surface with a razor ground flat on the under side and oiled, the integument being held tense and slightly pushed up by a hand above and one below the place from which the grafts were to be cut; the razor was not permitted to penetrate beneath the papillary layer of the skin. The strips were cut about an inch wide and as long as possible; they very much resembled wet tissue paper, and as they were cut heaped themselves up on the razor-blade. They were then transferred, right side down, directly upon the surface to be grafted, by seizing the end of the strip at the edge of the razor, bringing it to the edge of the wound, and then gently drawing the razor away from this point in the direction of the surface that the graft was meant to cover. No antiseptics were used during the entire process of grafting and dressing; salt solution alone

Hosted by Google

was used as an irrigant. The grafts slightly overlapped each other in all directions and were covered with strips of Lister protective or gutta-percha tissue; a copious dressing of gauze wet with salt solution was placed outside, a sheet of gutta-percha tissue was wrapped over the whole, and finally a wet gauze bandage was applied with moderate firmness. Before applying the dressing all air-bubbles, blood-clots, or whatever might prevent contact of the grafts with the granulations were squeezed out. The dressing was kept wet with salt solution for forty-eight hours, and the dressing was then renewed, the surface being sprayed gently with hydrogen dioxide in salt solution (half and half), washed off with salt solution, and dressed as at first, save that it was not necessary that the gauze should be kept wet. By this process, repeated some dozen times in the course of a year, a true skin was made to cover the whole area that had sloughed away. It was even moveable freely over the underlying tissues at all points and much elastic tissue developed, so that upon the thigh and calf the skin could be drawn away from the subjacent structures for a distance of an inch. Sensation returned completely throughout the new skin, there was no contraction at the flexure of the knee-joint or elsewhere, and so far as appearances went the leg was in perfect condition. The grafts were taken from the opposite thigh, the thigh upon the injured side above the lesion, and both upper arms. These regions, which yielded successive crops of grafts at intervals of about six weeks, appeared to be in their normal condition save for slight discolourations. The hair was growing over them all as usual, proving that only superficial layers of skin were taken away. The surfaces healed over, as a rule, after taking grafts in about two weeks. These raw surfaces were covered by strips of protective and a dry gauze dressing and bandage. Simple dusting with formaldehyde-gelatin, without other dressing, had also proved satisfactory.

MEDICAL AFFAIRS IN MADAGASCAR.

GENERAL GALLIÉNI, Governor and Commander-in-Chief of the new French colony, has promulgated the following *arrêté*:—"1. No one shall be allowed to engage in the practice of medicine in Madagascar and its dependencies unless he is furnished with a diploma of doctor in medicine of a French faculty. 2. Only natives who have obtained their diplomas in one of the French schools of medicine established in the colony shall be considered as doctors in medicine of a French faculty and authorised to practise in Madagascar. 3. Physicians and surgeons possessing foreign diplomas, no matter what their nationality may be, can only exercise their profession in Madagascar and its dependencies on condition of having obtained, before a French faculty, the diploma of doctor in medicine in conformity with the dispositions specified in Article 5, Chapter iv., of the Law of 30th November, 1892, on the practice of medicine." As a transitory measure medical men possessing foreign qualifications who are at present in practice in Madagascar may obtain authorisation to continue the exercise of their profession provided they make application for it in proper form, and at the same time submit their credentials for examination and verification. In order to afford natives an opportunity of becoming qualified a school of medicine has been opened at Antananarivo under the direction of a military surgeon named Métayer. The selection of a military man for the post has been severely criticised in the Parisian medical press. It is not as though civilian professors were a rarity in France, exclaims one writer indignantly, seeing that they are so numerous they cannot all find employment. It is said to be the wish of the authorities to encourage emigration into Madagascar, but here is an opportunity of introducing emigrants of the very best quality, under whose skilled impulsion the nascent Malgash university could not but speedily attain to the desired standard of perfection. An army surgeon doubtless knows better than his civilian *confrère* how to manage the soldier and keep him up to the mark as a fighting machine, but the professional upbringing of embryonic medical practitioners is another affair altogether, and by no means a military speciality. The pupils being all destined for civil employment it certainly does seem reasonable that their instruction should be entrusted to civilians, but in the present case economy may possibly have something to do with the censured arrangement. The military surgeons must be on the spot in any case, and having as a rule a good deal of leisure the additional occupation thus offered them is no doubt welcome. From another French source we learn that ever since the English Isoavinandriana hospital was requisitioned for the sick and wounded of the army of occupation the want of an establishment where the indigent natives could obtain medical and surgical aid has been grievously felt. In order to fill the void a new hospital has been installed at the expense of the Malgash Prime Minister Rasanjy, who contributes, moreover, the annual sum of £480 towards its maintenance. The balance required, which is estimated at £400 per annum, is to be provided out of colonial resources.

FRESH-WATER BIOLOGY.

THE success and interesting results which have attended the establishment of fresh-water biological stations on the Continent and elsewhere have prompted the question as to why England is behind in this matter. Mr. Scourfield, in a recent number of *Natural Science*, pleads for that impetus to the study of the fauna and flora of English fresh waters which the establishment of stations would give in this country. In a later number of the same journal (March, 1897) Professor Anton Fritsch, Ph.D., of Prague, expresses his pleasure on learning of this proposal, and he records how interesting and various has proved the study of the life groups in more than thirty kinds of Bohemian fresh waters, each with its own special fauna and flora, and comprising springs, mountain brooks, mountain rivers, rivers of the plain, backwaters of large rivers, ponds, lakes, bogs, small pools with *Apus*, snowtarns with *Branchipus*, &c. Each of these kinds of water varies in its own fauna with the seasons of the year and also from year to year, according as rain and sunshine also vary. "Here," remarks Professor Fritsch, "is a work for a century," and we would add that to many it should prove a pleasant and recreative study. The movement is surely a worthy one, and in the interests of science and even national affairs should be supported.

REMUNERATIVE PHILANTHROPY.

WHEN in 1891 Lord Rowton and Mr. (now Sir) Richard Farrant started the common lodging-houses known as Rowton Houses, it was thought doubtful whether such superior accommodation at so low a price could be made to pay; but so successful was the first venture that a company which paid 4 per cent. was soon formed, and with the new capital two more houses were started. The first of these was opened in May of last year and the other is very near completion. The excellence of the accommodation provided has already been referred to in our columns,[1] and we have only to again congratulate Lord Rowton, Sir Richard Farrant, and the company upon the result of their praiseworthy enterprise. The third annual report states that the balance to the credit of the revenue account, after placing £800 to reserve for repairs and renewals, writing off the preliminary expenses amounting to £269 19*s.*, and paying the preference dividends to Dec. 31st, 1896, amounts to

[1] THE LANCET, April 25th, 1893, and March 28th, 1896.

Hosted by Google

£5017 12*s*., out of which the directors recommend that a dividend at the rate of 5 per cent. per annum be paid on the ordinary shares for the year ending Dec. 31st, 1896. This will absorb £3625, leaving £1392 12*s*. to be carried forward. Rowton House, Vauxhall (484 cubicles), has been fully occupied throughout the year, and the receipts have been slightly in excess of those of the previous year. Rowton House, King's-cross (678 cubicles), continues to be fully occupied. Rowton House, Newington-butts (800 cubicles), is practically complete and is now being roofed. The operations of the company are, we are glad to hear, to be greatly extended and the capital of the company is to be increased by £100,000.

HORSELESS CARRIAGES IN AMERICA.

To a physician in Youngstown, Ohio, is due the distinction of being the first medical man in the United States to make use of a motor carriage for the purpose of working his practice. Dr. Carlos Booth terms his vehicle a motor cab, has used it for several months, finds it an excellent substitute for one drawn by a horse, and prefers it in most respects to that animal as a motive power. In this carriage Dr. Booth has attained a speed on the level of ten miles per hour, and climbed an incline of from 10 to 15 per cent. grade at the rate of five miles per hour. It seems that motor carriages should prove especially useful to the general practitioner, and particularly to the country one, on whose shoulders the burden of maintaining the two or three horses, with their attendant expenses, necessary for a large and scattered practice falls very heavily. At present the initial cost is large, but, on the other hand, the cost of working horseless carriages is small and the country roads of England, unlike those of America, are peculiarly well adapted to their use. Cripples, paralytics, and those who retain the use of their arms but have no control over their lower limbs should find these vehicles of the greatest service; they would not only be able to travel by means of them without assistance, but also be able to amuse themselves with corresponding benefit to their health.

CONGENITAL SPASTIC RIGIDITY.

CONGENITAL spastic paraplegia was first drawn attention to by von Keine as early as 1840, by Little in his work on "Deformities" in 1853, and by the same writer in the Obstetrical Transactions for 1862, and is sometimes known as "Little's disease," although this term is practically confined to a certain class of cases only—namely, those which occur in children born before full term or at term with the use of instruments. A more recent criticism occurs in an editorial article in the *Medical News* (New York) for Feb. 6th of this year. The symptoms are now generally recognised, the physical condition consisting of diplegia of a spasmodic type, most marked in the lower extremities, where it constitutes a condition of paraplegic contracture, whilst there is also a marked psychical defect, consisting of lack of proper and timely developments of the mental processes, which is very rarely of such a degree as to constitute a mild form of idiocy. Little's disease, however, although dating from birth, is not usually recognised until a number of months later. The pathology and morbid anatomy of the disease are still very obscure. In recent numbers of the *Journal de Neurologie* observations on this subject have been published by van Gehuchten. He points out that congenital spastic rigidity is most common in children born prematurely; it matters very little whether the birth be an easy or a difficult one. At this time of life the pyramidal tracts are almost wholly non-medullated, and therefore devoid of the ability to perform their function. The first tracts to become medullated are those constituting the indirect motor pathway—the pathway through the pons cerebellum; while the direct pathway—the cortical spinal fibres—are very much delayed in acquisition of myelin sheaths and perhaps may never develop them at all. In its downward growth during the later years of infancy the tract of the cortico-spinal fibres reaches first the upper and then the lower levels of the cord, those fibres destined for the lumbar and sacral portions requiring the longest time to reach their destination. The course of symptoms of this disease corresponds with these observations; the rigidity disappears first in the face and head, then in the upper extremities, and remains longest, and perhaps does not disappear at all, in the lower extremities. Van Gehuchten maintains, therefore, that the absence of the myelin sheaths of the cortico spinal fibres constituting the pyramidal tract is attended by the same symptoms as degeneration of these fibres. In both conditions there is an absence of inhibitory action of these fibres upon the motor ganglion cells of the anterior horns, and hence the spasticity. As the author of the article (Dr. Joseph Collins) suggests, these recent writings of van Gehuchten commend themselves to the reader because of the closeness of reasoning contained in them, especially reasoning from analogy on well-founded anatomical facts, and the attention of investigators will be called to the necessity of more accurate and trustworthy observations concerning the genesis and time of occurrence of the disease.

CORONER'S INQUESTS IN LIVERPOOL DURING 1896.

THE total number of cases of death reported to, and investigated by, the city coroner amounted to 1570. In 563 of these cases inquests were deemed unnecessary. Inquests were held in 1007 cases, including 583 males and 424 females. Of these, 106 were legitimate male infants and 101 legitimate female infants, all under one year. Of the illegitimate infants under one year there were 6 males and 11 females. Fifty inquests were held on male children of one year and under seven years. Of children of seven years and under sixteen years there were 28 males and 21 females. Of youths of sixteen years and under twenty-five years there were 24 males and 17 females. In adults of twenty-five years and under sixty years the figures are 306 males and 177 females. Above sixty years of age 63 males and 53 females are accounted for. Post-mortem examinations were made in 147 instances. 189 deaths were due to excessive drinking; of these, 118 were males and 71 females. Sad to say, 185 infants were suffocated whilst in bed with parents or otherwise. Verdicts of "murder," "manslaughter," and "justifiable homicide" were returned in 5, 12, and 1 cases respectively. Verdicts of "accidental death" were recorded in 363 cases; the number of inquests on the bodies of newly born infants was 18. No verdict of "felo de se" is recorded.

DIPHTHERIA AND SCHOOLS.

DR. MEREDITH RICHARDS, the medical officer of health of Chesterfield, furnishes in his annual report for 1896, instances of the manner in which schools may be instrumental in conveying diphtheria, even although the persons attacked may not be at school ages or attending a school which has been recognised as being infected. In the instances brought forward by Dr. Richards evidence is adduced tending to show that the notified cases which were not attending school contracted the disease from school children who apparently for some time past had suffered from slight sore-throat or enlarged cervical glands, and from the throats of whom the bacilli of diphtheria were procured. In the case of one of the schools in question it was ascertained that a teacher had some weeks previously suffered from diphtheria. It is quite clear that in discussing

Hosted by Google

the effects of school influence in the spread of diphtheria, regard must be had to the indirect as well as to the direct mischief thus caused, and that to assume the absence of diphtheria from a school because no case of the disease has been notified therefrom is an assumption which is not likely to aid epidemiological research. Notification is obviously a most useful agency for the control of infectious disease, but it involves so many uncertain factors that it only furnishes partial information, and those who proceed to investigate outbreaks of disease having regard only to recognised and notified cases are liable to obtain fallacious results. No one would go so far as to assert or to assume as a basis for investigation that schools are always in actual operation for harm, but at the same time no epidemiologist would, it is to be hoped, deny that at times when diphtheria possesses a high degree of infectivity schools present favourable opportunities for the dissemination of the disease.

THE PREVENTION OF TUBERCULOSIS.

THE present time is eminently suitable for the discussion of this subject, inasmuch as the Royal Commission which is now sitting cannot but derive assistance from papers and debates calculated to thrash out the relative importance of the several preventive measures intended to diminish the prevalence of this disease, which enacts such a heavy death toll every year. Dr. Niven's name is intimately associated with this subject, and although the position which he has taken up is perhaps regarded by many as somewhat a counsel of perfection, nevertheless all students of public health have great respect for his opinions and will be very glad to hear the arguments which he will bring forward to-night (Friday) at the Epidemiological Society. The subject is one of great national, and even international importance, and it affects not only medical officers of health, but also every medical man throughout the country. If the notification of tuberculosis were made compulsory the relations of every medical practitioner with his patients would be affected; and it is to be hoped that the debate will be well attended by those who are familiar with the pathology of the disease as it manifests itself amongst our infantile population as well as in adults. We hear that Dr. Payne and Dr. Sidney Martin are expected to join in the discussion.

A DISTINCTIVE SIGN FOR RUSSIAN MEDICAL PRACTITIONERS.

THE Medical Council of the Ministry of Internal Affairs, the highest authority on all medical matters in Russia, has recently decided to introduce a small *znak*, or sign, to be worn on the breast by all medical men, as a sort of insignia of their profession. The idea is not a new one. For many years past all Russian medical men with the degree of Doctor of Medicine have worn, or at least had the right to wear, a little silver sign of this sort. It is of oval shape, about one and a half inches long and one inch broad, and bears a raised design of two intertwined serpents. Under the new regulation—which is not yet law, but will probably very soon become so—this same *znak* will be worn by all qualified practitioners, whether they have the higher degree of M.D. or only the lower qualification of *lékar*. The question was discussed whether some new decoration of special design should not be instituted for those who have taken their doctorate; but this was decided in the negative for the present, so that for the immediate future all Russian medical men, without distinction of degree, will wear the same sign. The object in introducing the sign appears to have been the hope that some distinction of this sort would increase the safety of the wearer in the less civilised parts of the country. Medical men, it was argued, in dealing with epidemics have frequently to take very decisive action on the frontiers and among the uneducated peasantry, and often run great personal risks if the opposition of the people is aroused. The cholera riots of a few years ago, in which many medical men lost their lives, were eloquent proofs of the dangers which medical men often have to face. The sign on the breast will, it is thought, be a certain protection, particularly for civilian practitioners, who have no uniform to show their official position. It will show that the wearer is a servant of the Tsar, and in this way will, it is hoped, command the respect of the people and enable medical men to carry out sanitary and hygienic measures without opposition.

THE CLINICAL RESEARCH ASSOCIATION.

WE have received an advance copy of the annual report of the Clinical Research Association, a body which has only been in existence for a little over two years and has a membership of more than 2400. During the last twelve months 7227 specimens were submitted for examination, of which 1710 were chemical, 3804 bacteriological, and 1532 histological. These figures represent an enormous amount of work, the value of which as a means of establishing diagnosis and so of facilitating treatment cannot be too highly estimated. A new department has been opened for medical photography, including x ray work, and a portable sterile swab for obtaining and transmitting material from the throats of patients suspected of suffering from diphtheria has been devised and is supplied gratuitously on application.

LUNACY IN SYRIA.

MR THEOPHILUS WALDMEIER, a veteran missionary in the East and formerly one of the Abyssinian captives under King Theodore, has taken up the cause of the insane in Syria and Palestine. At present there is no provision in these provinces of the Turkish Empire for the care of lunatics, beyond the convents, to which they are often taken in order that the monks may exorcise the evil spirits by which they are supposed to be possessed. Torture and even death result from the inhuman treatment practised, whilst demented persons often wander at large in the country, like the demoniac in the tombs, untended and ill-used. Mr. Waldmeier, after long study of their condition, has originated a proposal for an asylum to contain 80 or 100 lunatics, which is to be built on the most approved cottage system at the foot of Mount Lebanon, near to the large town of Beyrout. The leading practitioners at this town, American, British, and native Syrian, have given the scheme enthusiastic support and formed an executive committee to promote it. A committee has also been formed in London, consisting of Dr. Percy Smith of Bethlem Royal Hospital, Dr. R. Jones and Dr. F. R. P. Taylor of Claybury Asylum, and Dr. Whitcombe of Birmingham, besides others interested in missionary work abroad — Dr. Gilbart-Smith, Dr. John Dixon, and Dr. Hingston Fox—and several well-known lay members. A meeting was held at the Bethlem Royal Hospital on March 11th. Plans of the proposed buildings were produced, which had been approved by Dr. Clouston of Edinburgh, Dr. Yellowlees of Glasgow, and Dr. Bedford Pierce of York, all of whom have taken the warmest practical interest in the undertaking. Mr. and Mrs. Waldmeier have visited many of the best asylums in Great Britain as well as in Switzerland and Germany in order to become acquainted with the best methods, both of construction and organisation. They will take back with them a specially qualified British physician to have medical charge of the asylum. Sir Richard Tangye, who is treasurer to the fund, reported that nearly £3000 of the total of £10,000 required had

Hosted by Google

been contributed or promised. The work will be a pioneer one in Syria, and the new asylum or home will form an object lesson to the country and a token of advancing civilisation, and will, it is hoped, lead to a kinder and more humane treatment of the sick in mind throughout the Orient.

HEALTH OF THE GOLD COAST.

AT a time when considerable public attention is being directed to the West Coast of Africa, owing to the return of punitive expeditions from the interior and the establishment of gold-mining companies on the coast, it is useful to acquire all available information dealing with the climatic conditions of the country. In the last Colonial Report from the Gold Coast it is stated that 'the general health of the colony was extremely bad, the endemic fever assuming a pseudo-epidemic form of a malignant type, closely approaching in its clinical manifestations the yellow fever of the West Indies. The death-rate among Europeans was very high, and the excitement induced thereby amounted at one time almost to a panic and served to intensify the fatal tendencies of the prevailing fever. To insanitary causes, aggravated by the excessive humidity of the atmosphere, high shade temperature and practically no rainfall intensifying the action of pathogenic organisms of every kind and especially the endemic malarial poison, must be attributed the malignant type of the fever."

CONGENITAL DEFECT IN THE PECTORAL MUSCLES WITH WEBBED FINGERS.

IN the last number of the *Neurologisches Centralblatt* a short abstract appears of a paper in Virchow's *Archiv* by Professor Hoffmann of Heidelberg concerning a very interesting condition of congenital defect. The patient was a man aged forty-seven years, in whom the sternal part of the right pectoralis major was entirely absent, the clavicular portion of the muscle as well as the pectoralis minor being well developed. The whole of the right upper extremity was shorter and of smaller diameter than the left. The fingers of the right hand had assumed the claw position and some of the joints were ankylosed. Between the right index and middle fingers, as well as between the latter and the ring finger, there was a web which reached to the middle of the first phalanx, while between the ring and the little fingers the web extended between even the first phalanges. There was no sensory impairment, and in spite of the atrophy the right arm was as strong as the left. Professor Hoffmann has collected from medical literature no less than ten cases of defect in the pectoral muscles with webbing of fingers on the same side. In the majority the defect was found in males and affected the right side. The deformity is no doubt the result of a defect in development.

THE ANTI-QUACKERY LEAGUE.

WE have received a circular issued by the above league, giving an account of its aims and objects, which are the "exposure and repression of quackery." The league intends to arrange for the "distribution of books to public libraries and of leaflets for general and local circulation, showing the gross imposture and the worthless composition of quack medicines, the folly and credulity of people who are duped by false assertions of curative power, and the physical injury and pecuniary loss resulting from the use of these nostrums." The league also intends to supply the book, "Exposures of Quackery," to free libraries throughout the kingdom. We welcome the foundation of this league most heartily, but the Augean stable of quackery needs a very Hercules for its cleansing. Perhaps the best way would be to petition the Legislature to absolutely prohibit the sale of proprietary medicines and make them all patent medicines, so that a description of them could be readily consulted by the public, or, still better, a full description of the composition should be printed in large letters upon every bottle or packet containing the nostrum. No one should be allowed to manufacture quack medicines of any description without paying a heavy licence, and the various scoundrels who batten on the public and masquerade under the title of "Reverend" should be imprisoned for fraud, especially that pestilent section of them which professes to cure "self abuse." Any newspaper which inserts advertisements of these remedies should be compelled to hand over any profits over and above expenses to an asylum for idiots, and anyone who sends filthy pamphlets through the post which are dropped into letter-boxes should upon conviction be imprisoned and his whole stock confiscated. Those desirous of joining the league are requested to apply to the Secretary, Anti-quackery League, Savoy House, Strand, London. The minimum subscription is 2*s.* 6*d.* a year.

THE IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION: THE FESTIVAL DINNER.

THE Festival dinner of this association was held at the Café Monico on the evening of St. Patrick's day, the 17th inst., when Professor Alexander Macalister, F.R.S., Professor of Anatomy at Cambridge University, presided over an enthusiastic gathering of upwards of 200, including several ladies. Among the guests were Lord Lister, Sir John Gorst, M.P., Professor Jebb, M.P., and Sir Ambrose Shea, K.C.M.G. The toast of "The Services" was proposed in eloquent terms by Mr. George Stoker, and replied to by Sir James Dick, K.C.B., and Surgeon-Major-General Taylor, C.B. Dr. Cagney proposed "The Guests," to which toast Lord Lister, Sir John Gorst, and Sir Ambrose Shea replied. Professor Clifford Allbutt proposed the toast of "Prosperity to the Irish Medical Schools and Graduates' Association," to which the chairman responded. The speeches were alternated by songs of a national character, and the vocalists were enthusiastically applauded. It was the opinion of all present that a very enjoyable evening had been spent and that hearty thanks were due to Mr. O'Callaghan and Dr. Cagney, the organisers of the meeting.

THE LOCAL OR GENERAL REJECTION OF DISEASED MEAT.

WE are glad to see that the Portsmouth magistrates by a decision given the other day in police-court proceedings do not intend to countenance the idea that if part of a beast is infected with, and rejected on account of, disease other parts may be freely sold and eaten for human food. A butcher was charged with exposing for sale a tongue, heart, two pieces of liver, half a head, and two pieces of suet, all of which were unfit for food. Further, it was alleged he had in preparation for sale two sides and three skirts of beef unfit for food. The inspector said that they were diseased with tuberculosis, and the whole was condemned and destroyed. All the glands were diseased and the deposits could be seen with the naked eye. The defence was based on some parts of the report of the recent Royal Commission, in which it was said to be stated that if meat in which tuberculosis was found was properly treated much of it would be fit for food. It was admitted that this cow was a little "grapy"—which, it was explained, was a butcher's term for this disease—but it was argued that if the "grapy" parts had been removed the flesh would be fit for food, and one witness said he would not be backward in eating it himself. This point the magistrates settled by fining defendant £11 and £1 2*s.* costs. Another point, that the law only allowed an urban sanitary authority to appoint

Hosted by Google

one sanitary inspector and that the town council had no power to appoint assistants—the inspector in this case was one of the latter—the bench settled on the common-sense argument that with but one officer they did not see how large cities and towns could be adequately protected.

MRS. PEMBERTON, the widow of Mr. Oliver Pemberton, F.R.C.S., the coroner for Birmingham, did not long survive her husband. He died on Sunday, March 7th, and Mrs. Pemberton died on the following Saturday. She was seventy years of age, and the only daughter of Daniel Whittle Harvey, M.P., the first Chief Commissioner of the City of London Police, and a man of considerable political importance. We offer our sincere condolences to the family upon their double bereavement.

THE Queen has granted unto Mr. Harry Maule Crookshank, F.R.C.S. Edin., Her Majesty's Royal licence and authority to accept and wear the Insignia of the Imperial Order of the Osmanieh of the second class, in recognition of his services while actually and entirely employed beyond Her Majesty's Dominions in the Khedive's service as Inspector-General of Egyptian Prisons.

A PUBLIC meeting to promote the National Jenner Memorial will be held in the theatre of the University of London, Burlington House, on Wednesday, March 31st, at 4 P.M. His Grace the Duke of Westminster will preside. Among the speakers will be Lord Herschell, Lord Playfair, Lord Lister, and Professor Michael Foster.

THE Queen has been pleased, on the recommendation of the Secretary for Scotland, to appoint Sir Henry Duncan Littlejohn, LL.D., M.D. Edin., to the Chair of Forensic Medicine in the University of Edinburgh, in the room of Sir Douglas Maclagan, LL.D.Glasg., M.D. Edin., resigned.

THE discussion on Retro-ocular Neuritis begun at the meeting of the Ophthalmological Society on Thursday, the 11th inst., will be continued at an adjourned meeting of the society to be held on Wednesday, March 24th, at 8.30 P.M.

PROFESSOR E. VON BERGMANN, Berlin; Professor Felix Guyon, Paris; Sir W. Hales Hingston, Montreal; and Dr. T. G. Roddick, Montreal, have been elected Honorary Fellows of the Medical Society of London.

MR. WELLINGTON LAKE, medical officer of health of the Guildford and Woking districts of West Surrey, has been appointed deputy-coroner for West Surrey.

BIRMINGHAM GENERAL DISPENSARY.—The annual meeting of the Birmingham General Dispensary was held on Feb. 24th, Alderman G. J. Johnson presiding. The report showed that the total number of patients admitted during the year by ticket was 35,098, an increase of 2324 on the previous year. The total income for the year was £7662. A new branch was opened at Small Heath last year, making the fifth branch which had been added to the parent institution during its hundred years of existence.

ROYAL NATIONAL PENSION FUND FOR NURSES.—The annual meeting of the members of the Royal National Pension Fund for Nurses was held on March 11th at the offices, 28, Finsbury-pavement, E.C., Mr. W. H. Burns, the chairman, presiding. The report showed that over eight hundred nurses had joined the fund during 1896, and the invested funds had risen from £256,600 to £311,200. Sick pay amounting to £1158 had been distributed. The Junius S. Morgan Benevolent Fund had now been brought up to £16,000 by donations received partly from nurses and partly from members of Mr. Morgan's family.

The Lancet Special Commission ON THE METROPOLITAN WATER-SUPPLY.

V.[1]

THE SOUTHWARK AND VAUXHALL WATERWORK COMPANY.

History.

FOR a long time the supply of water to the district south of the Thames was even more unsatisfactory than that to the north of the river. The district is a low-lying one, with surface water which is not good, and the inhabitants were, comparatively speaking, poor. In the year 1767 a lease of the fifth arch (from the north and the second from the south) of London Bridge was granted by the Lord Mayor and Corporation of the City, that water-wheels might be put up for the supply of South London, and the work was carried out by the London Bridge Waterworks Company. Southwark was also partly supplied by works from a pond in St. Mary Overie. Neither of these businesses, however, was in a flourishing state at the time of the destruction of London Bridge. They were carried on in rivalry, and pipes from both supplied the same streets. A considerable outlay had been necessary to place the water-supply in an efficient state. A private individual named Edwards bought the Borough works at St. Mary Overie in 1820, and in 1822 he purchased the London Bridge works from the New River Company. He united them in one business, called the Southwark Waterworks, erected steam-engines, and gradually substituted iron pipes for the wooden ones that had been previously used. A change was also made in the method of taking water. Up to that time it had been obtained from a point near the shore; a large iron main was now carried to the middle of the river, and the mouth of the conduit which conveyed it to the wells was covered with a perforated semi-spherical iron cap. The intake was 8 ft. below low-water mark and an iron grating was put at the end of the conduit next the engine well. Before being distributed the water passed through another wire interceptor, but no other method of purification was adopted and there was no reservoir. To obtain the necessary pressure for the delivery of water it was pumped to a cistern which was raised about 60 ft. from the ground and was capable of holding 300 or 400 barrels of water. The engine power was sufficient to raise 4,000,000 gallons a day. The amount of water supplied was only about 1,500,000 gallons and the number of houses supplied was about 7000, and amongst the customers were the great hospitals of the Borough: Guy's and St. Thomas's. The mains extended for a distance of about two miles from the works.

Up to the year 1804 South London was supplied by the Southwark Company, of which an account has just been given, and the Lambeth Company, and the water was sent directly from the Thames to the houses without being kept in a reservoir or undergoing any purification except that of passing through a wire screen. In the year 1805 a number of persons united to form a new company, and an Act of Parliament was obtained in July that year. The amount of money originally raised was insufficient to carry out the work required, and another Act was obtained in 1813 to increase the capital, but the Company had to borrow exchequer bills in 1823. At the early part of its career the Company lost a good deal of money by adopting wooden pipes for the distribution of water, for it was soon found that it was necessary to substitute iron pipes for those which had been put down. The principal station of the Company was near Vauxhall at the south side of Kennington Common. The company was unfortunate also in the selection of their steam-engines. Those first supplied were too small. In 1822 one of 45-horse power was erected and this was capable of pumping the water to a height of 65 ft. above the level of the reservoirs. A little later another engine

[1] Nos. I., II., III., and IV. were published in THE LANCET of Feb. 20th, 27th, and March 6th and 13th, 1897, respectively.

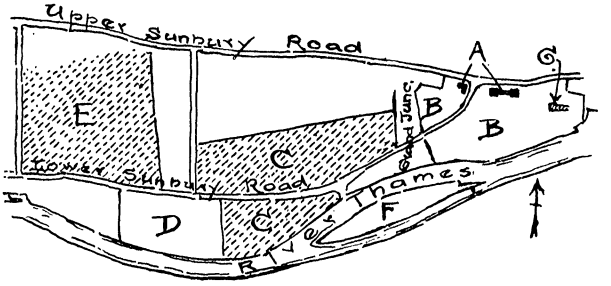
Hosted by Google

was put up at Cumberland-gardens, near Vauxhall Bridge, to pump the water to Kennington-lane. The water flowed from the river through an iron tunnel 42 in. in diameter. The intake was placed in the stream as far as the third arch of Vauxhall Bridge and at a level of 6 ft. below low water mark. The station at Kennington-common had an area of about five acres and two reservoirs were erected there. Both were lined with bricks and had sloping sides. During spring tides the water flowed from the Thames to the reservoirs and filled them to a level of 6 ft. but they could only be completely filled by pumping. When full one of the reservoirs was capable of holding 2,000,000 gallons of water and the other rather less. A few years later a third reservoir was erected to receive water from the Thames through an iron tunnel 4 ft. in diameter which had already been put down. From the new reservoir water percolated through a filtering bank made of gravel and sand and passed into another reservoir, where it remained for some time before going to the engine well. The second reservoir was several feet lower than the other and was used for keeping the mains full during the night in case of fires. The total capacity of the reservoirs in 1835 amounted to 6,000,000 gallons. The Company were able to supply water to a height of 70 feet above the level of their reservoirs. At this date they supplied about 10,000 houses, and their Act allowed them to supply parts of Lambeth, Newington, Bermondsey, Rotherhithe, Deptford, Camberwell, and Clapham. They were prevented from laying down pipes to any houses within one and a half miles of the Lambeth works. The Lambeth Company, however, were allowed to lay down pipes within 200 yards of the reservoirs of the South London Company. "Thus," as a contemporary writer points out, "restraints were imposed upon one concern and a privilege conferred upon another not in strict accordance with the primary object of legislation, which ought rather to aim at promotion to benefit the security of the community." The restraints to which reference has been made were done away with by an Act passed in 1834. The new Act made it necessary also for both Companies to supply filtered water.

In the year 1845 the Vauxhall Company united with the Southwark and became the Southwark and Vauxhall Water Company. Land was immediately bought at Battersea, so that all the work might be carried on from one station. Water was taken from the Thames at Battersea, subsiding reservoirs and filter beds were constructed, and pumping engines and a stand-pipe were erected. In 1851 it was decided to change the source of the supply from Battersea to Hampton, and an Act was obtained for this purpose in 1852. Reservoirs were made at Hampton, and the necessary plant was put up to pump the water to Battersea. The pumping arrangements at Battersea were altered and new filter beds constructed there. In 1856 additional pumping power was arranged for at Battersea, and in 1862 another engine was put up at Hampton. In 1866 additional works were made at Hampton—a river wall was built, a subsiding reservoir and three filter beds were constructed, and the pumping power was increased. A new main was made to Wandsworth. In 1871 four covered service reservoirs were commenced at Peckham. Of these reservoirs two were 168 feet and the other two 200 feet above ordnance datum. Engines were also erected at Peckham. In 1881 a deep well was commenced at Streatham. In 1884 an arrangement was made for obtaining water from the gravel beds at Hampton. In 1886 additional new engines were put up at Hampton, and an Act was passed to allow the Company to put up a high service reservoir at Forest-hill and for laying a new main between Hampton and Nunhead. In 1891 the pumping station at Wandsworth was erected for the supply of Forest-hill and that district.

Present State: General Description.

The Southwark and Vauxhall Company supplies Petersham and a district skirting the south bank of the Thames from Kew to Rotherhithe, including Mortlake, Barnes, Putney, Roehampton, part of Wimbledon, Wandsworth, Battersea, part of Clapham, Lambeth, Kennington, Newington, Walworth, Camberwell, Bermondsey, and part of Dulwich.



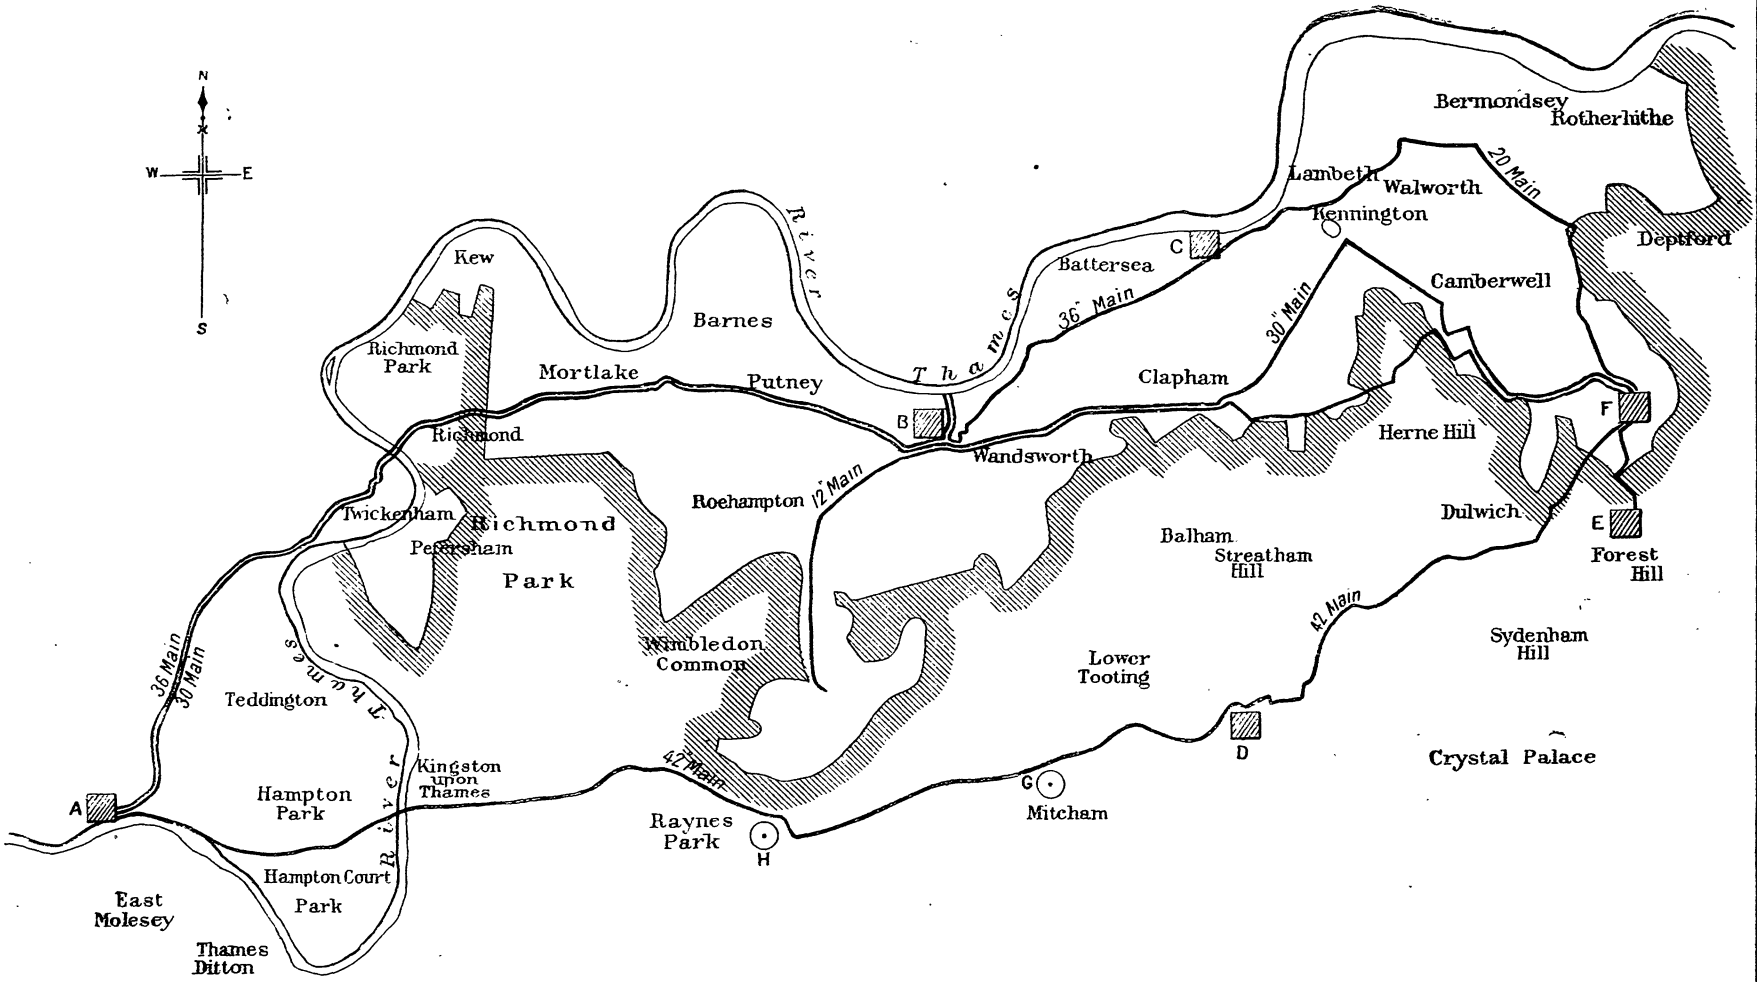
The sources of supply are: (1) the Thames at Hampton; (2) gravel beds near the Thames at Hampton and Platt's Eyot; and (3) a deep well at Streatham.

The stations of the Company, indicated upon the map, are six in number: A. Hampton and Sunbury, Middlesex, and Platt's Eyot, Surrey (Intake, gravel water collecting grounds, reservoir, filter-beds, and pumping station). B. Wandsworth (pumping station). C Battersea (reservoirs, filter-beds, pumping station. D. Streatham (deep well, pumping station). E. Forest-hill (reservoir). F. Nunhead (reservoir, pumping station).

A deep well is being sunk at Merton Abbey and trial boring operations are in progress at Raynes Park. The sites of these operations are marked on the Map G and H respectively.

Hampton.—The station at Hampton is situated between the Upper Sunbury-road and the River Thames, almost entirely in the parish of Hampton; there is, however, a small piece at the east end of the property in the parish of Sunbury, and an island called Platt's Eyot in the River Thames, and this belongs to the county of Surrey. Extensive changes are now being made at this station, and it may be best to give first a general description of what is going on, which will be realised most easily by referring to the accompanying plan (Fig. 1). The parts which are not

FIG. 1.



General plan of the Company's Station at Hampton, Middlesex. A, G, Engine houses. B, Filter beds. C, Land from which water is collected from the gravel beds. D, E, Reservoirs. F, Platt's Eyot.

undergoing any changes are the engine houses marked AA, and the filter beds marked BB, some of which are situated to the north and some to the south of the Lower Sunbury-road. The land immediately to the west of the existing filter beds belongs to the Grand Junction Company, and on going further in a westerly direction down the Lower Sunbury-road the next part belonging to the company, marked C C, is land from which water is collected from the gravel beds. The system adopted here will be described later. At present it is sufficient to point out that part of this collecting ground is situated to the north and part to the south of the Lower Sunbury-road, and that extensive changes are taking place in both these areas. The part to the north of the road is to be used for new filter beds and a reservoir, the part to the south of the road for filter beds. Going still to the west along the Lower Sunbury-road it is seen that the Company have a reservoir to the south of the road, marked D; and farther on to the north of the road two extensive reservoirs, marked E, are in course of construction. Platt's Eyot, marked F, from which water is collected from the ballast, will not be affected by the changes now in progress. At the extreme east of the Company's property a new engine house is in course of construction, and the site of this is marked G in the plan. The parts of the Hampton station in which work is now being carried on are marked with shading in the diagram, C, C, E, and this brief description and a glance at the map will show that active operations are being carried on at the present time.

Water from the gravel beds.—The part of the station at Hampton which is devoted to collecting water from the gravel beds occupies two fields, one to the north, and one to the south of the Lower Sunbury-road, and the greater part of Platt's Eyot, (see Fig. 2). The area of the two fields is about thirty-two acres, and that of the island rather over seven acres. Water was formerly admitted from the Thames to the fields through a vertical gravel filter, sections of which are shown in the diagram (see Figs. 3 and 4). The ballast was thus filled with water by means of earthenware pipes which are laid with open joints. The diagram (Fig. 2) shows the way in which these pipes are arranged. Water thus artificially introduced into the gravel bed from the Thames, after passing through about 50 ft. of gravel and sand, is collected by a system of 24-in. pipes, which are laid with open joints at a level of some feet lower than that of the distributing pipes and just on the surface of the

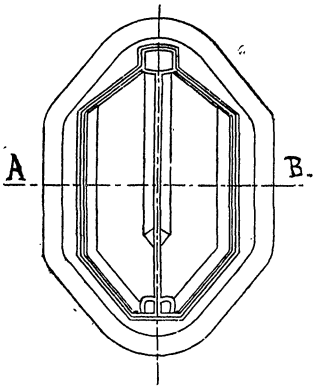

FIG. 2.

Plan showing arrangement of the collecting pipes (C) and the distributing pipes (D) on the Hampton gravel beds.

London clay. The distribution of the collecting pipes is shown in the map. It will be seen that they all converge to one point. Here there is a well. The water is conveyed thence through two 36-in. conduits to an engine house and then pumped up 14 ft. to the filter beds. The accompanying

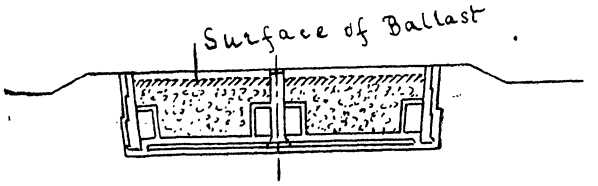

FIG. 3.

Horizontal section of the vertical gravel filter through which water was admitted to charge the ballast in the collecting ground.

diagram shows in vertical section the arrangement of the distributing and collecting pipes (see Fig. 5). The upper pipes, marked D in the drawing, are the distributing pipes; those marked C, which are on the surface of the clay, are the collecting pipes. The arrangements for flooding the ballast are now in course of removal.

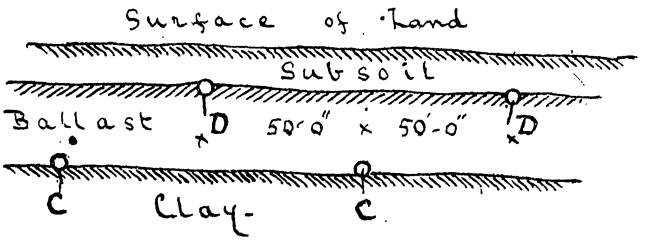

FIG. 4.

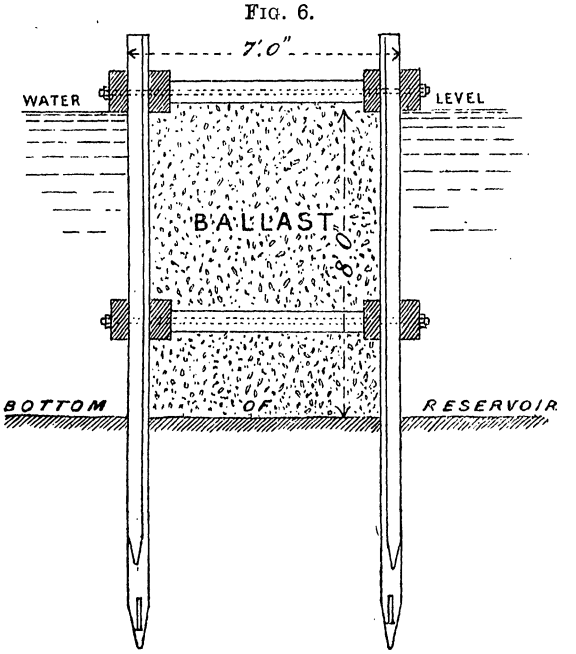
Vertical section of vertical gravel filter in the previous figure through A B.



Platt's Eyot.—There is a cutting from near one end of the island to the other, and through this the water from the Thames flows. The flow of the water is regulated by gates situated at each end of the cutting. The island itself is formed chiefly of gravel, and in the gravel beds collecting pipes similar to those which are used on the mainland are placed. These collecting pipes are situated about 9 feet below the ordinary level of the Thames; the river water has therefore to pass through several feet of ballast before it gets

FIG. 5.

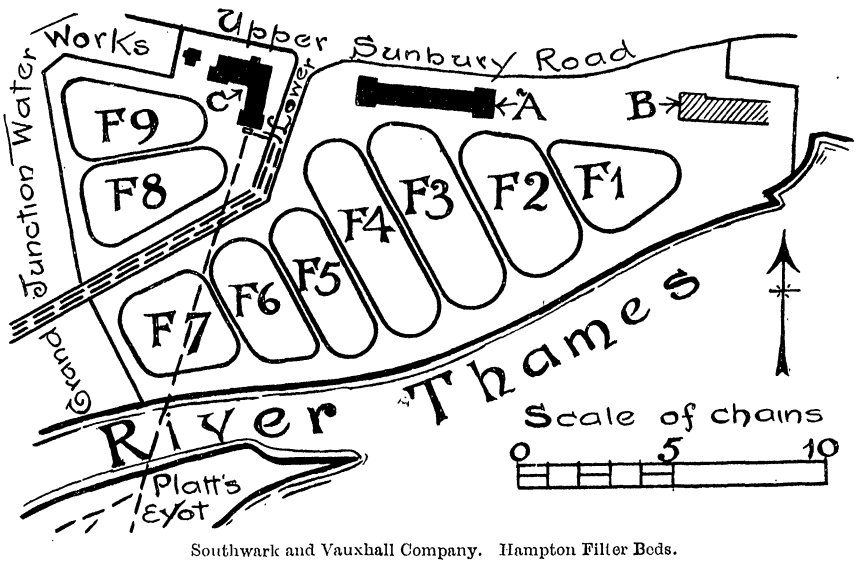
into the collecting pipe. From these pipes water is conducted through a tunnel 5 ft. in diameter which passes under the Thames to the engine well, from which it is pumped to



Hosted by Google

the filter beds. When the Thames is in high flood, water is not pumped from the island.

Intakes from the Thames.—There are three intakes from the Thames: (1) the new intake, used for the first time last summer to fill the new reservoir; (2) the middle intake; and (3) the old intake, situated near the filter bed marked 7.

At the new intake there are three bays. The water passes through a screen which is formed of ¾ in. bars, and through three sluices into an irregular octagonal reservoir. When visited on Dec. 9th, work was in progress here. A new engine house was completed and one engine was erected, and a second was in process of being erected. The engine

FIG. 7.

Southwark and Vauxhall Company. Hampton Filter Beds.

in working order is a triple-expansion high-speed engine, driving centrifugal pumps, the indicated horse power being 160; the steam is generated by four water-tube high-pressure boilers. The new reservoir, which was first filled during the summer of 1896, has a capacity of 90,000,000 gallons. It is faced with bricks and concrete. When visited on Dec. 9th water from this reservoir was being drawn for the supply of the filters. The Thames was in flood and turbid.

From the second or middle intake the water is conveyed through a 36-in. conduit, and passes through a vertical iron screen similar to that at the new intake. The water is then admitted to the filter beds. At the old intake there are six bays, and the water passes through a screen which is formed of ¾-in. bars, and is then conducted through three 36-in. pipes to the filter beds. A vertical filtering screen (Fig. 6), of which a drawing is given, was formerly in use at Hampton. This system was found to be unsatisfactory, chiefly from the fact that the work of cleaning it involved much trouble, because it entailed moving and replacing the whole of the ballast.

Filter beds.—There are nine filter beds at Hampton. Of these two are to the north and the others to the south-west of the Lower Sunbury-road and close to the Thames. The total area occupied by the filter beds is nine acres. They were not all made at the same date and are not constructed in exactly the same way. Their general form will be seen by looking at the accompanying diagram (Fig. 7). The earliest filters are those numbered 2, 3, 4; these were made in the years 1868–9. The sides of these beds are not vertical, but are arranged at a slope of 1½ : 1. The newer filter beds have almost vertical sides. There is one other point of difference. In the older beds the filtered water channels have central upright ventilators, in the case of the newer beds the ventilation is carried out by means of shafts situated at the sides of the beds. All the filters have central channels for the collection of the filtered water, which passes into them through agricultural tiles. The sand is cleansed by washing under high pressure.

(To be continued.)

ANNUAL REPORT FOR 1895 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

FIRST NOTICE.

MR. SHIRLEY MURPHY has recently issued his annual report as medical officer of health to the London County Council. The present volume, which relates to the year 1895, makes the fourth of the series that was commenced in 1892; it extends to 134 folio pages, and is arranged on the same general plan as were its three predecessors.

Having regard to the high degree of importance attaching to an authoritative treatise on the public health of the metropolis, we have devoted more than ordinary attention to the volume before us. The work is thoroughly well done and will fully sustain the high reputation of the author. Comparing the present report with the first of the series we are impressed with the amount and elaborateness of statistical detail with which its pages abound, not less than with the evidence it affords of steady improvement in the practical sanitary work achieved by the local boards since the establishment of a coördinating central authority. Like that of its predecessors, the subject matter of the present report is divided into two sections—the first dealing with statistics and the second with sanitary administration.

The London Census which was taken last March showed that the population of the administrative county has not been increasing since 1891 quite so rapidly as it had done between 1881 and 1890. Estimated on the assumption that the rate of increase has been constant since 1891 the population of the administrative county of London in the middle of 1895 is believed to have numbered 4,402,284, or 11,217 less than it would have been had the rate of increase obtaining between 1881 and 1890 prevailed since the latter date. In thirteen of the London sanitary districts there has been a decrease of population since 1891, whilst an increase has taken place in the remaining districts. In only twelve of the latter districts, however, was the increase greater than the excess of births over deaths in the five years 1891–95.

The London death-rate in 1895 is given as 19·9 per 1000, which becomes 21·2 on correction for age and sex constitution of the population. Applying the same principle of correction to the sanitary areas of London it is shown in a useful table that if the death-rate of London as a whole be taken as 1000 the rates of twenty-four of the sanitary districts exceeded that rate whilst the remainder were in defect of it. Comparing the London death-rate at all ages in the five years 1891–5 with that of the previous decade, there was a decrease equal to 3 per cent. among males and 2 per cent.

Hosted by Google

among females. A table is given showing the fluctuations of mortality in these two periods at the several periods of life. Examination of this table shows that the fall in the death-rate at all ages is mainly due to a decrease at ages under forty-five years, for the death-rate of both males and females above that age has for some reason increased. Pursuing the subject further, Mr. Shirley Murphy shows by another table that within the last five years there has been a mean annual saving of 1304 lives, and that this represents 85,519 years of "life capital" annually saved to the community. The actual gain is therefore greater than would appear from the number of lives saved, and this is evident from the great saving of life at the earlier ages which is shown by the table

Turning now to that portion of the report which deals with the prevalence of common infectious diseases it is at once apparent that by the passing of the Diseases Notification Act the sanitary authorities of the metropolis have acquired more effective powers for grappling with these diseases, especially in relation to the attendance of children at school. Statistics are rapidly accumulating with respect, not to mortality alone, but what is infinitely more important, to sickness also, from these diseases in London, and Mr. Shirley Murphy is to be congratulated on the lucid manner in which he presents these statistics in his successive annual reports. The question of small-pox *mortality* in London during 1895 has been already noticed in connexion with the Registrar-General's annual summary; Mr. Shirley Murphy, however, furnishes particulars of the incidence of *attacks* by this disease in the course of the year. It appears that from the beginning of 1895 to its close not a single week passed in which one or more cases of small-pox did not occur. Towards the end of June the attacks rapidly increased in number, and from that period until the middle of October fears were entertained lest this disease should become epidemic in London. The eastern parts of the metropolis were specially affected, the disease being communicated by tramps, and spreading to neighbouring places from Whitechapel, which suffered more severely than other sanitary areas. In connexion with the subject of small-pox prevalence in London the Medical Officer of Health again draws attention to the large increase in the number of children appearing in the vaccination returns as "not finally accounted for" in recent years. In 1893, the latest year for which returns are available, the proportion so returned was equal to 18·2 per cent. of the total births. "The neglect of vaccination in London in recent years," says Mr. Shirley Murphy, "appears to be already manifesting itself by an increase in the proportion which deaths of children from small-pox bear to deaths from this disease at all ages."

The mortality from measles was rather below the decennial average in London as a whole. The eastern districts suffered more severely than the others from this disease, but the highest mortality occurred in St. Luke's sanitary area, the adjoining areas of Holborn and Clerkenwell also suffering severely.

Scarlet fever was somewhat more prevalent in 1895 than it had been in the previous year, although from the case fatality it may be gathered that the type of disease was milder In the present, as also in previous reports, a diagram has been inserted showing the relationship of school attendance to scarlet fever prevalence. The diagram for 1895 shows a marked diminution of scarlet fever incidence in the month of August, which corresponds with the summer holiday. The curve shows a fall in the week immediately following the commencement of the holidays and a rise in the week immediately succeeding their termination. In this respect the statistics of 1895 appear to confirm those of recent previous years as regards the County of London, at any rate. In proportion to population the eastern districts of London suffered more severely than other districts in 1895 in respect both of the number of attacks and of the number of deaths. The outbreak of scarlet fever in Islington in the course of the year was caused by an infected milk-supply, which gave rise to as many as 125 cases in that district alone.

The incidence of diphtheria sickness in the County of London during 1895 corresponded exactly with that of the previous year, but was less than that of 1893. Judged by the "case fatality," however, the type of the disease seems to have been milder in 1895 than in either of the two preceding years. The question of how far this reduction in case fatality may be related to the more frequent use of antitoxic serum in 1895 in the treatment of diphtheria is discussed by Mr. Shirley Murphy in the text, and interesting statistics are given bearing upon this relationship.

As in the case of scarlet fever, a diagram is inserted showing the distribution of diphtheria attacks in the several weeks of the year. From this diagram it appears that there was a considerable diminution in diphtheria prevalence in the holiday month of August corresponding exactly with the diminution in the attacks by scarlet fever. As in some previous years, the diminished prevalence among children under three years of age occurs somewhat later than among children of school age, suggesting, in Mr. Shirley Murphy's opinion, that the decrease among infants resulted from diminished opportunity of infection from older children. The heaviest incidence of this disease was upon the eastern districts of London generally, but the district of Greenwich had the highest case-rate during the year. In proportion to population the incidence of sickness from enteric fever in 1895 did not differ greatly from the average in the previous four years. In this year, as in the previous decade, the eastern group of districts had the highest death-rates from enteric fever and the western districts the lowest. An unusually heavy incidence of the disease was experienced at Plumstead, where as many as 215 cases were reported, giving an attack-rate of 3·7 per 1000.

The mortality from phthisis in the administrative county of London was heavier in 1895 than in the preceding year. The rates of mortality from this disease ranged from 1 55 in the western group of sanitary areas to 2 05 in the eastern group and 2 65 in the central. The lowest rates were 0 87 in Lewisham, and the highest 3·28 in St. Saviour's Southwark and 3 31 in St. Giles's.

THE INTERNATIONAL SANITARY CONFERENCE.

FROM Venice, under date March 13th, our Special Correspondent writes:—

The regulations of arrivals from ports on the Persian Gulf engaged the attention of the Conference for several sittings, and the following measures were discussed and approved:—

A ship arriving from one of these ports and certified as infected must immediately disembark its patients, who will at once be isolated. The other passengers will also have to land and subject themselves to surveillance for a period not exceeding ten days. Soiled linen and articles in personal use will be disinfected, as also the ship itself in that part or parts of it deemed necessary by the authorities.

Suspected ships—those, that is to say, which have had cases of the "pestis" on board, but have had no fresh case for twelve days—will undergo a medical visit. The linen, the wearing apparel, and such like which the authorities may pronounce contaminated will be disinfected. The passengers and the crew will be subjected to a ten days' surveillance. The bilge water will be emptied out, the hold and ballast disinfected, and good potable water supplied.

Immunised ships will have free course, provided always that they have completed ten whole days since their departure from the last infected port, otherwise they will have to remain under surveillance until the expiry of this period. All the same, the authorities at the port of arrival will have it in their power to prescribe and enforce the measures adopted for suspected ships. In applying these measures in circumstances as they arise the authorities, however, will have to make allowance for the presence on board of a medical man provided with disinfecting apparatus, since, as already stated, in such cases the measures taken will be less vigorous.

Special measures will be authorised for adoption in regard to certain ships, especially those conveying pilgrims, and, indeed, for all others found in bad hygienic condition. Ships declining to undergo the measures prescribed by the authorities will have it in their power to put back to sea. Their passengers, however, will have the right to demand disembarkation provided that they submit to the measures prescribed by the authorities of the port at which they want to land.

The Conference next resolved upon the construction of two hygienic establishments in the Persian Gulf—one in the district of Ormuz or in the Island of Ormuz, or in that of Kishm; and the other in the neighbourhood of Bassora, at a suitable point to be subsequently agreed upon. Each of these establishments will be fully equipped with a medical staff, with sanitary officers and warders, with disinfecting

Hosted by Google

apparatus, and with hospitals on a small scale. They will further possess commodious "lazzaretti," while all the ships before entering the Persian Gulf will have to undergo the discipline of the establishment and submit to the regulations prescribed. Such ships, however, as have not been "cleared" from surveillance and which have to re-ascend the Chat-el-Arab, will be authorised to continue their voyage; but only on condition that they take on board the sanitary warders, who will hold them under surveillance as far as Bassora for the second medical visit and for the prescribed disinfections.

Those ships which have to disembark goods or passengers at the Persian ports will have to do so at Bender-Bushire, when there has been constructed there a suitable hygienic station. Pending this they will have to do it at Ormuz or at Bassora.

However, such ships as have been immunised for ten days will have in each case free course into all the ports of the Persian Gulf, after their state of immunisation has been officially confirmed.

A NEW AND MODEL CONVALESCENT HOME FOR WORKMEN.

THE Rustington Convalescent Home for Working Men will be inaugurated to-day (Saturday). This in many respects is a model institution. It is situated on the beach, close to Littlehampton, faces the sea, and is well exposed to the sea breezes. Built of red brick with a green slate roof and a copper-covered domed clock-tower, it stands out boldly and has a monumental aspect when viewed from the Littlehampton sea parade. No expense has been spared. The instructions to the architect and builder were to err on the side of extravagance rather than on the side of parsimony. The principle governing the plans executed is that in the long run money will be saved, because the solidity of the materials employed and the soundness of the workmanship will obviate the necessity of constant repairs. Though there are no elaborate art decorations, the excellence of the materials and their æsthetic colours rest and please the eye. For instance, glazed bricks are extensively utilised. These are cream white and olive-green, while the wood is so hard that no paint is required. There are no less than seventeen rooms which contain but one bed each. Ten rooms contain two beds each, and only two rooms hold four beds. This provision for forty-five patients could be raised to sixty if the rooms now allotted to the servants were utilised for the patients. Every effort will be made to make the patients feel thoroughly at home, instead of being treated as if they were paupers in receipt of charity who have to be kept well in hand by the enforcement of stern discipline. On the contrary, all the attendants have received instructions to treat the patients as if they were guests. The engine-house is to be thrown open to inspection, and every information given that may instruct or interest the inmates of the home. There is no knowing to what extent kindness of this description may awaken a dormant thirst for higher knowledge, and how far, by satisfying the mind and intelligence, a convalescence may be hastened to a happy issue. Thus on the ground-floor there is a large entertainment hall, where lectures and concerts can be given. Then there are a smoking-room and a reading-room, and bagatelle and other games. There is also a "quiet room," where patients may rest undisturbed on sofas, and need not when exhausted go to their bedrooms. The grounds comprise about nine acres, with a sea frontage of 575 feet, and at the back there is a small pinery, where in summer the shade of these fragrant trees can be fully enjoyed. Numerous seats, some in sheltered positions, and an outhouse for smokers afford the means of rest while taking gentle exercise, and this without quitting the premises. In one corner of the building, and communicating with the gardens, there are lavatories and a boot-room, where the patients can put on their slippers before entering the main building.

The home throughout is lighted by electricity and all the services are worked by electric power. A separate building contains the boiler, dynamo, and engines, and everything is in duplicate so that there shall be no breakdown. Above the engines there is a model power laundry with all the most recent machinery. Windows on both sides admit ample ventilation and light, while powerful Boyle extractors will draw the air and damp out through the roof. A screw propeller fan, worked by electricity, supplies hot air to the drying chamber. It is a pity that similar air propellers have not been placed within the home itself. The care taken to ensure ventilation is more elaborate than scientific. The corridors are warmed by hot-water coils, and apertures above the doors enable the warmed air from the corridors to enter the rooms. On the opposite side, by the outer wall, there is at least one Tobin tube and in the large rooms several such tubes. Every room also has an open-grate fireplace, and above the fireplace an opening, protected by mica valves, which serves to extract the foul air. Thus when both windows and doors are shut there still remains ample means of ventilation; but this ventilation must of necessity depend on the force and direction of the wind, on the difference of the in-door and out-door temperature—in a word, on varying climatic conditions. It will, therefore, be too violent at some moments and insufficient at others. This is inevitable in all buildings excepting those that are provided with motive power. With power, however, the supply of air can be regulated with mathematical precision. It then depends on the velocity of the revolving fans, and not on the force of the wind and the fluctuations of the temperature. At the home power is employed to pump the fresh and the salt water into the tanks, to raise the lifts, to work the machinery in the laundry, and even to pump hot air into the drying chamber; but, strange to say, it is not employed for ventilation.

Hot and cold and salt and fresh water baths are provided on every floor. The outer walls are of double thickness with a two-inch vacant space, or "air blanket" between each wall. The window frames have a weather dip of two and a half inches and an oak sill. The urinals have a curled lip all the way down both sides. This is Mr. Bostel's patent, and it prevents splashing and keeps the clothes away. Above there is an automatic flush tank, and below an automatic syphon. The soil pipes have inlet and outlet ventilators protected by charcoal, and there is a very elaborate flushing of the closet pans. The fresh-water supply is derived from an artesian well fifty-five feet deep. This water is softened by Maignen's process and then pumped to the top of the building, where the fresh-water tanks can hold 3000 gallons. Here there is a very ingenious apparatus for automatically setting the electric pump in motion. As the water level in the tanks falls the floater acts upon a brass tube balanced on the wall of the tank loft. When the tube is so pressed down as to reverse the level a steel ball, which is inside and at the other extremity of the tube, runs down, and its weight causes this tubular brass rod to fall with violence, so that it strikes the electric apparatus with sufficient and sudden force to establish the current and set the electric pump in motion. When the tanks are full pressure on the other side of the tube reverses the action, and the tube, swinging back to its original position, stops the pump. Thus, by the automatic see-saw of this brass rod the tanks are re-filled as soon as they become empty. This apparatus is known as Bostel's automatic lever switch, and we had the satisfaction of seeing it work very effectively.

Altogether we were most favourably impressed by our visit to this new convalescent home, and are convinced that its future inmates will greatly benefit from their sojourn in an institution which is so admirably built and situated. The scheme was originated by Mr. Thomas Noblett, who had recognised the great difficulty encountered by workmen and others in gaining admission to convalescent homes. A workman may be ordered to the seaside by his medical attendant, but often he has not the means to pay for lodgings, &c. He may then obtain a list of subscribers to existing homes, and apply vaguely to one and the other. No answers are received, and much time is lost. Mr. Noblett therefore helped to organise the North-West London Convalescent Home Fund and placed himself in communication with the clergy, the medical men, the missionaries, and the benefit sick clubs of his district, so that knowledge of deserving cases might be obtained and the patients sent to convalescent homes without any loss of time. From the very first Mr. Noblett obtained generous support from Mr. Henry Harben of Hampstead, and finally Mr. Harben decided to erect at his own expense the home we have just described. The cost has exceeded £50,000, and to this Mr. Harben will add an endowment of £20,000. This generous initiative will, it is to be hoped, be strengthened by public subscription, a guinea subscription entitling to one letter of recommendation.

Hosted by Google

Patients, also, unless absolutely destitute, will be expected to pay at least 5*s*. a week.

MIDWIVES REGISTRATION BILL.

A MEETING in support of the Midwives Registration Bill was held at 73, Chester-square, on March 10th, Lady Balfour of Burleigh, president of the Central Association for Promoting Compulsory Registration of Midwives, being in the chair. Lady Balfour opened the proceedings with a few remarks, after which Mr. Heywood Johnstone, M.P., in the course of a speech said that a committee of the House of Commons took a considerable amount of evidence on this subject in 1892 and 1893, and presented an absolutely unanimous report in favour of a measure of this kind. The present Bill does not prevent anyone resorting to the assistance of a friendly neighbour, no matter how unqualified for the special purpose. What it says is that every person who calls in the aid of a midwife shall have some security, if she wishes, that she is employing one who is competent to undertake the case. It further provides for the creation of a board having a large preponderance of medical practitioners, which board is to draw up certain rules, and among them rules for assigning due limits to the practice of registered midwives; so there is no reason to fear that the practice of medical men will be encroached upon.

Dr. CULLINGWORTH then addressed the meeting, his remarks being substantially as follows:—"An appalling amount of illness is inflicted upon the women of the poorer classes in consequence of the attendance given them during their confinements by ill-trained and ignorant persons who assume the title of midwife. A few evenings ago, when delivering my inaugural address as President of the Obstetrical Society of London, I had occasion to state that although improvements in obstetric science have largely reduced the mortality among parturient women wherever they are applied, yet the general mortality from puerperal fever either remains where it was, as is the case in London, or is actually on the increase, as is the case in the provinces of England and Wales. It prevails most where there is a scattered and mining population, or where, as in the mountainous parts of Wales, the attendance of medical men is rendered extremely difficult, and the care of the mothers is in the hands of untrained midwives. In addition to this mortality there is also a very large amount of disease among women of the working classes wholly due to mismanagement during their confinements. Another very serious matter is that the most usual cause of blindness is infantile ophthalmia, a preventable disease which would not occur in the practice of a conscientious midwife possessed of the most elementary training. The Obstetrical Society of London has long been of opinion that women who call themselves midwives should be required to have some knowledge of the duties which they undertake, and also that a certain amount of supervision should be exercised over them. For many years the society urged upon the Legislature the need for dealing with this question, and in 1872 instituted their examination in midwifery as a temporary expedient until a satisfactory measure should be passed. I was examiner at the Obstetrical Society for some years, and can bear witness that women who have undergone even three months' training have been able to attain that kind of elementary practical knowledge which we consider essential. The clause regarding control is one of the most important in the Bill; it is suggested that in each sanitary district the medical officer of health is the proper person to undertake the duties of local supervision, and in the event of his being unwilling to act the county council may select some other practitioner for the work. I am extremely glad to be here to show that the medical profession is not, as a whole, opposed to this measure. In my opinion, objections to the Bill on the ground of interference with the medical profession are founded upon a fallacy. I have no desire to see my profession suffer, and I honestly believe that this measure will not have such an effect."

Mrs. HEYWOOD JOHNSTONE having read the rules of the West Sussex Association and said that the present meeting was intended to inauguarate that branch, made a short speech in favour of the Bill, after which the proceedings terminated.

THE MEDICAL DEFENCE UNION.

THE annual general meeting of the Medical Defence Union, Limited, was held on Feb. 25th, in the rooms of the Medical Society, 11, Chandos-street, Mr. Victor Horsley, F.R.S., the President, being in the chair.

The report of the council upon the work of the union during 1896 showed some excellent results; not only were the applications made by members for aid, advice, and assistance increased in number, but the value of the union is evidently becoming more understood by the profession generally and more appreciated by the members themselves. The legal work during the past year has been exceedingly heavy and the expenditure has been proportionally higher, notwithstanding the fact that the legal adviser of the union has in many cases succeeded in obtaining payment of the costs from his opponents. In addition to the gratifying amount of success in the law courts, there is good reason for believing that the mere fact of its being known that the union was about to take action greatly facilitated the obtaining of apologies for, and retractations of, various slanders made against individual members. The council is strongly of opinion that nothing short of an amendment to the Medical Act, 1858, making it penal for any person to practise any branch of medicine or surgery for gain without being registered, will succeed in effectually checking unqualified practitioners. When offenders are brought before the law courts it is found that decisions directly opposed to each other are given in cases which appear to be quite similar. In London the council obtained a conviction against an individual who practised under the name of John Ferdinand, M.D. U.S.A., but in another part of the country a prosecution of a like kind was unsuccessful, and on an appeal being made to the High Court the Judges of the appellate Court supported the magistrate who had refused to convict. The council of the union has under its consideration a draft Bill on the subject, and will probably, in conjunction with the British Medical Association, lay it before the Government next year in the hope that it may be adopted as a Government measure. The negotiations for amalgamation with the London and Counties Medical Protection Society were apparently on the point of being brought to a successful termination when they were broken off in consequence of a difference of opinion as to the title of the new association. It is stated that the Medical Defence Union desired to add to its title the words "with which is amalgamated the London and Counties Medical Protection Society, Limited," and that this arrangement was refused by the council of the latter society, who insisted that their proposed name should be adhered to and that the title should be registered.

The council publishes a list of ninety-seven cases, in which with very few exceptions the result of the action taken by the union was highly satisfactory. The solicitor also contributes a supplementary report, in which he mentions that during the year upwards of 150 separate cases had been legally advised upon and conducted by him upon the instructions of the union. On Dec. 31st the union had 3832 names of members on its register, 351 having been added during the year just closed. The offices are at 20, King William-street, Strand, W.C.

THE PLAGUE IN INDIA.

THE reports from India are, on the whole, more hopeful and promising, those from Bombay city showing a decided improvement. The Plague Committee are working systematically and well, and there is on all sides a good deal of energy displayed in dealing with the disease and in the hygienic improvement of matters generally. There is no concealment or official reticence about the work that is being done; on the contrary, everything is open to the inspection of foreign medical missions and visitors from foreign countries. The officials afford any information in their power, and their arrangements can be ascertained by anyone who cares to take the trouble. The total plague returns for Bombay city up to the 11th inst. (according to Reuter's telegraphic agency) amount to 9032 cases and 7546 deaths.

Hosted by Google

The week's mortality from all causes in Bombay was 1326, as compared with 1484 in the previous week; and the returns for the whole Presidency since the outbreak of the plague up to the 6th inst. amount to 14,856 cases and 12,204 deaths.

The Secretary of State for India has received an official telegram from the Governor of Bombay of a decidedly satisfactory character. The Plague Committee in Bombay, says Lord Sandhurst, are working well and successfully. In spite of the opposition of the natives to the organisation of hospital work, the cases in Bandra, Coorla, and the Thana district have diminished in number. The number of persons who have been inoculated is not precisely known, but it is not less than 2790. The result of Dr. Yersin's treatment is not yet stated.

It will be remembered that many persons were disposed to think that there was some connexion between the outbreak of plague and the storage of grain, and Surgeon-Colonel Waters some time ago gave an interesting account of his researches into the origin of plague, in which he adverted to the rat murrain that had been noticed in several of the outbreaks of bubonic disease and to the plausible hypothesis that the disease might be connected with something affecting the granaries and the storage of the cheaper varieties of grain and millet. Mr. Hankin reports, however, that he has examined a large number of specimens of grain and flour under various conditions, but has been unable to detect the plague microbe in any of them, and that his examination of weevils and of other parasitic insects has also been with negative results. M. Haffkine has been busily occupied in developing a prophylactic and antitoxic serum. It is yet too early to pronounce any opinion on their efficacy, but the antitoxic curative serum has already been tried in many cases of plague in the Arthur-road Infectious Disease Hospital, Bombay, and in the Byculla gaol with, so far, promising results. Dr. Yersin, who was one of the first observers of the plague microbe in China in 1894, and who has worked on the subject in that country and subsequently at the Pasteur Institute in Paris, has prepared a stock of antitoxic serum, and we shall soon know whether the results obtained in India are confirmatory of those which Dr. Yersin and others obtained in China. Dr. Yersin's presence in Bombay is attributable to some extent to Lord Lister's influence and to the highly favourable opinion he had formed of the antitoxin treatment of plague.

CONVESAZIONE AT ST. GEORGE'S HOSPITAL.

A VERY largely attended conversazione organised by the staff of St. George's Hospital was held in the medical school on March 13th. The guests were received by the senior physician (Dr. Cavafy), the senior surgeon (Mr. Pick), and the dean (Dr. Isambard Owen). In the museum and the newly opened laboratories were a number of most interesting exhibits, and in the dean's room a collection of school records, including a number of relics of John Hunter, various letters from him, and his ticket of admission as a student. In the museum there were a number of recently added specimens prepared by the formalin method, described by Kanthack and Shaw at the Pathological Society on Nov. 3rd, 1896, which retained their colour, we had almost said, in a life-like fashion. These specimens were prepared and exhibited by Dr. Cyril Ogle. Dr. Patrick Manson showed a very complete series of slides illustrating the life-history of the malaria parasite, the same slides from which the drawings were taken to illustrate Dr. Manson's Goulstonian Lecture delivered before the Royal College of Physicians of London and published in THE LANCET of March 14th, 21st, and 28th, 1896.

Mr. Clinton Dent showed an interesting collection of skiagraphs in the small lecture theatre, and Mr. Adams Frost gave a lantern demonstration of ophthalmoscopic appearances, while in the large theatre Mr. Gardner gave a demonstration of liquid oxygen, and at another period of the evening, with the assistance of Mr. Cockburn, showed a number of experiments at low temperatures. In the new physiological laboratories Dr. Buckmaster and his assistants were in charge of various physiological and anatomical exhibits. Two specially noteworthy were the circulation of the blood in the yelk sac of the embryo trout, where, owing to the absence of any elastic tissue, the blood circulated in jerks corresponding to every beat of the heart, instead of, as in the frog's web, running regularly, and a micro-spectroscopic demonstration of the power of cilia to reduce hæmoglobin, thus illustrating cell respiration. Among the anatomical specimens were some most exquisite sections of the minute anatomy of the nervous system, especially some preparations of Purkinje's cells. In the bacteriological laboratories Dr. Slater and Dr. Fison showed various methods of bacteriological investigation, together with the methods of serum diagnosis employed by Widal and others. Excellent lantern demonstrations were provided, and the micro-photographic work of Mr. E. J. Spitta was much admired; while in the pathological laboratory Dr. Rolleston exhibited sundry rare pathological conditions illustrated by microscopic sections. Among them were an implantation cyst, sections of a sarcoma before and after the injection of Coley's fluid, and a series of adenomata from various parts of the body.

In the lower physiological laboratory Dr. Buckmaster showed a number of experiments illustrating the fatigue of muscle and nerve. This laboratory is fitted with all the newest appliances, and the recording drums, &c., are driven by a small water motor.

In the department of anatomy Mr. G. R. Turner showed a very beautiful series of specimens illustrating the development of the osseous system in the fœtus, the specimens of the vertebral column being most notable. The house physicians and surgeons were indefatigable in conducting numerous parties of visitors over the new operating theatres, built by Mr. Percy Adams upon the most modern principles, but they were so fully described in our issue of Jan. 23rd last that there is no need to say any more about them here. Along with all these intellectual delights the weaknesses of our nature were provided for by refreshments and tobacco, and entertainment on a higher plane was provided by the Hemming Quartet, who played in the corridor. Mr. Turner and the other demonstrators are entitled to our gratitude for their courtesy and kindness in showing everything there was to be seen and for the trouble they took in explaining the various exhibits.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on March 11th, the President, Sir WILLIAM MACCORMAC, being in the chair.

The Secretary reported the death of Mr. Oliver Pemberton, member of the Council, and a resolution was carried unanimously in which the Council recorded "their deep regret at the death of Mr. Oliver Pemberton, whom they highly esteemed as an able colleague, keenly interested in the welfare of the College and the advancement of surgical science, and in all the relations of life upright, honourable, and true," and expressed "their very sincere sympathy with Mrs. Pemberton and her family in their great affliction."[1]

Mr. William H. Bennett and Mr. W. Johnson Walsham were elected members of the Court of Examiners, and Mr. Davies-Colley was elected a member of the Board of Examiners in Dental Surgery.

The best thanks of the Council were given to Mr. Christopher Heath for his Hunterian Oration, and he was requested to publish it.

A letter was read from Mr. J. H. Targett resigning his appointment as pathological curator. The resignation was accepted, but Mr. Targett was requested to continue his services for the present. It was referred to the museum committee to take steps for the appointment of a successor to Mr. Targett.

A requisition was received, signed by thirty Members of the College, for a meeting of Members to discuss resolutions relating to the following points: (1) the result and validity of the recent poll of the Fellows; (2) a proposal urging the Council to take a similar poll of the Members on the question of the representation of the Members on the Council; (3) the validity of the present mode of appointment of the

[1] We note with very great regret that Mrs. Pemberton herself died two days subsequently.—ED. L.

Hosted by Google

representative of the College on the General Medical Council; and (4) the refusal of the Council to carry out the by-laws in the case of Mr. R. B. Anderson. The Council resolved that the following reply should be sent: "The Council do not consider it desirable to summon a meeting of the Members for the objects specified in the requisition."

An address of condolence was received from the Obstetrical and Gynæcological Society of Berlin on the death of Sir T. Spencer Wells, Bart., past President of the College. It was resolved that the society should be informed that the Council gratefully appreciated their kind expression of sympathy.

A letter was read from the President of the Royal Society asking whether the College would support the following resolution adopted at a meeting of Presidents of scientific societies in London convened to consider whether any, and if so what, steps should be taken to commemorate the sixtieth year of Her Majesty's reign, viz.:—"That a fund to be called the Victoria Research Fund be established, to be administered by representatives of the various scientific societies, for the encouragement of research in all branches of science." The matter was referred to the President and the Vice-presidents to reply in sympathy with the objects proposed.

The President took the sense of the Council as to the propriety of the College taking some steps to celebrate the sixtieth year of Her Majesty's reign. It was resolved to send an address of congratulation, and it was referred to the President and Vice-presidents to consider and report as to a suitable method of celebrating the event.

A letter was read from Dr. R. R. Rentoul, calling attention to Clause 5 of the Midwives Registration Bill, and pointing out objections to it. A letter was also read from the Midwives Bill Committee, forwarding a copy of the Bill which has been introduced into the House of Commons, and expressing the hope that the Bill will meet with the approval of the College. These letters were acknowledged.

A report was read from Mr. Walter Rivington respecting his action as a representative of the College on the Civil Rights Defence Committee.

A letter was read from the Sanitary Institute inviting the College to send two delegates to the Congress of the Institute, which will be held at Leeds in September next. Mr. Jessop and Mr. Mayo Robson were appointed delegates.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chesterfield Urban District.—This district possesses a temporary hospital for the isolation of small-pox, but it has as yet no accommodation for ordinary infectious diseases. A site, however, has been procured, and Dr. Meredith Richards advises that one of the hospital committees of the Derbyshire County Council be approached with the view to a sort of joint scheme whereby the interests of the borough and part of the county may be simultaneously served. The Chesterfield Council refuse to supply disinfectants to the public for the purpose of "propitiating the germs" by exposing small quantities about an infected house; this procedure Dr. Richards points out is not of sufficient importance to be carried out at the expense of the town. The infantile mortality of Chesterfield during 1896 was 167 per 1000 births, and with a view of reducing this heavy toll efforts are being made to procure the services of a skilled nurse, who shall visit houses in which births have taken place and offer hints as to the preparation of infant food, &c.

St. Neots Urban and Rural Districts.—Mr. Poyntz Wright is strongly in favour of notification of measles in order that scholars from invaded houses may be excluded from school and, if necessary, the schools closed. In this matter of school closure Mr. Wright observes that although the children cannot be prevented from mixing together out of doors there can be no comparison between the risk of infection out of doors and that incurred in the vitiated atmosphere of a school with infected children therein. Mr. Wright also draws attention to the serious risks which are run by young children who are compelled to attend school in inclement weather, more especially so in rural districts, where long distances have often to be traversed, and where consequently the opportunities of getting wet are very considerable. In the urban district the Notification Act has been adopted, but apparently the council have declined to fix a date when the provisions of the Act are to come into operation. Surely the council should extricate themselves from this ludicrous position. In the report upon the Caxton and Arrington rural district, which is bound up in the same volume as that relative to St. Neots, Mr. Wright records an instance in which six friends dined together at a restaurant in Oxford-street, eating, amongst other things, oysters. A few hours after dinner all six were seized with cramps, vomiting, and purging, and six days later one of the six was notified as suffering from enteric fever. It is stated that the evidence pointed to the oysters as the cause of the mischief, and there is no doubt that many cases of severe gastric disturbances have at times followed the consumption of oysters, especially when such oysters have been procured from sources liable to pollution. As to the source of the enteric fever in the case above referred to, it can only be stated that six days is a somewhat short period for the development, recognition, and notification of this disease.

West Hartlepool Urban District.—Dr. S. Gourley reports in reference to infantile mortality that in cases where the evidence points to improper feeding as the cause of illness much good may be effected by threatening to refuse a certificate if the case should end fatally. He also observes that in West Hartlepool there is a remarkable coincidence to be noted in the association of bad feeding and insured lives, more especially in connexion with such insurance societies as pay more than the amount of the funeral fees and expenses. We read with interest in connexion with the public abattoirs of this district that during 1896 twenty-one beasts were seized and condemned for extensive tuberculosis. Six pigs and two sheep were also condemned as unfit for food. No settlement has, it appears, yet been come to in the matter of compensation for condemned beasts purchased in good faith.

Poole Urban District.—The provisions of the Notification Act in respect to dual notification are still well carried out in Poole, and Dr. Herbert Lawton tells us that during 1896 there were but eight instances in which the householder or nearest relative failed to notify to the medical officer of health. In referring to small-pox and the measures taken to control the disease Dr. Lawton observes, "I at once gave instruction to the public vaccinator to re-vaccinate." Surely Dr. Lawton is here somewhat anticipating the control which sanitary authorities may soon have over the machinery of vaccination.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6679 births and 3919 deaths were registered during the week ending March 13th. The annual rate of mortality in these towns, which had been 19·4 and 18·1 per 1000 in the two preceding weeks, rose again last week to 18·6. In London the rate was 18·4 per 1000, while it averaged 18·8 in the thirty-two provincial towns. The lowest rates in these towns were 12·2 in Newcastle-upon-Tyne, 12·8 in Huddersfield, 13·8 in Burnley, and 15·1 in West Ham; the highest rates were 23·3 in Liverpool, 24·5 in Bristol, 25·2 in Salford, and 25·3 in Bolton. The 3919 deaths included 334 which were referred to the principal zymotic diseases, against 378 and 331 in the two preceding weeks; of these, 83 resulted from whooping-cough, 79 from measles, 72 from diphtheria, 39 from diarrhœa, 38 from scarlet fever, 22 from "fever" (principally enteric), and 1 from small-pox. No death from any of these diseases was recorded in Norwich or in Newcastle-upon-Tyne; in the other towns they caused the lowest death-rates in Brighton, Burnley, and Hull, and the highest rates in Liverpool, Manchester, Salford, and Bolton. The greatest mortality from measles occurred in Cardiff, Manchester, Salford, and Bolton; and from whooping-cough in Swansea, Leicester, Sunderland, Manchester, and Nottingham. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 72 deaths from diphtheria included 53 in London, 4 in Liverpool, and 3 in Birmingham. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three towns. There were 30 small-pox patients under

Hosted by Google

treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 13th inst., against 34, 43, and 43 at the end of the three preceding weeks; no new case was admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2685, against 2901, 2817, and 2746 on the three preceding Saturdays; 218 new cases were admitted during the week, against 227, 237, and 211 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 368 and 307 in the two preceding weeks, rose again to 344 last week, but were as many as 230 below the corrected average. The causes of 44, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Cardiff, Leicester, Salford, Leeds, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Swansea, Birmingham, Liverpool, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the four preceding weeks from 28·8 to 24·9 per 1000, further fell to 23·1 during the week ending March 13th, but exceeded by 4·5 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·8 in Greenock and 18·2 in Paisley, to 24·6 in Dundee and 25·7 in Glasgow. The 690 deaths in these towns included 29 which were referred to whooping-cough, 27 to measles, 14 to diarrhœa, 5 to scarlet fever, 4 to diphtheria, and 4 to "fever." In all, 83 deaths resulted from these principal zymotic diseases, against 86 and 96 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2·8 per 1000, which was 1·2 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 32 and 36 in the two preceding weeks, declined again to 29 last week, of which 17 were recorded in Glasgow and 12 in Edinburgh. The deaths referred to measles, which had been 30 in each of the two preceding weeks, were 27 last week, of which 19 occurred in Glasgow and 7 in Edinburgh. The 5 fatal cases of scarlet fever corresponded with the number in the preceding week, and included 2 in Edinburgh. The 4 deaths from diphtheria also corresponded with the number in the preceding week, and included 2 in Glasgow, where 3 of the 4 fatal cases of "fever" were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 231 and 203 in the two preceding weeks, further declined to 152 last week, but were 46 above the number in the corresponding period of last year. The causes of 36, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 37·6 and 45·2 per 1000 in the two preceding weeks, declined again to 39·1 during the week ending March 13th. During the past ten weeks of the current quarter the death-rate in the city has averaged 40·7 per 1000, the rate during the same period being 18·6 in London and 22·4 in Edinburgh. The 262 deaths registered in Dublin during the week under notice showed a decline of 41 from the number in the preceding week, and included 61 which were referred to the principal zymotic diseases, against 55 and 79 in the two preceding weeks; of these, 43 resulted from measles, 9 from whooping-cough, 5 from diarrhœa, 2 from scarlet fever, 1 from diphtheria, and 1 from "fever." These 61 deaths were equal to an annual rate of 9·1 per 1000, the zymotic death-rate during the same period being 1·5 in London and 4·3 in Edinburgh. The fatal cases of measles, which had been 34 and 44 in the two preceding weeks, were 43 last week. The deaths referred to whooping-cough, which had been 12 and 21 in the two preceding weeks, declined again to 9 last week. The mortality from scarlet fever and from "fever" was below that recorded in the preceding week. The 262 deaths in Dublin last week included 43 of infants under one year of age, and 55 of persons aged upwards of sixty years; the deaths of infants were below those recorded in any recent week, while the deaths of elderly persons showed an increase. Five inquest cases and 5 deaths from violence were registered; and 70, or more than a fourth, of the deaths occurred in public institutions. The causes of 19, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR COATES embarks for Bombay, Surgeon-Major Boyd is to take Medical Charge of the troops at Armagh, and Surgeon-Major Carmichael proceeds to Cork for duty. Surgeon-Major Westcotte has been ordered to Dublin for duty. Surgeon-Major J. Tidbury has proceeded to the Southern District for duty, and Surgeon-Major Flood to the Belfast District.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Captain A. J. Heath (Bombay) are placed permanently at the disposal of the Government of Bombay. The services of the under-mentioned officers (Madras) are placed temporarily at the disposal of the Chief Commissioner of the Central Provinces for employment in famine and plague duty:—Surgeon-Lieutenants H. St. J. Fraser, M. Mathew, and F. L. Hammond. Surgeon-Colonel W. P. Warburton, Bengal Establishment, Inspector-General of Civil Hospitals, North-Western Provinces and Oudh, is granted the temporary rank of Surgeon-Major-General whilst officiating as Director-General, Indian Medical Service, and Sanitary Commissioner with the Government of India, during the absence on deputation of Surgeon-Major-General J. Cleghorn. Brigade-Surgeon-Lieutenant-Colonel T. H. Hendley, C.I.E., Indian Medical Service, Bengal Establishment, Residency Surgeon, Jeypore, and Administrative Medical Officer, Rajputana, is granted the temporary rank of Surgeon-Colonel whilst officiating as Inspector-General of Civil Hospitals, North-Western Provinces and Oudh, vice Surgeon-Colonel W. P. Warburton, appointed to officiate as Director-General, Indian Medical Service and Sanitary Commissioner with the Government of India. 2nd Bombay Lancers: Surgeon-Captain Jackson, officiating in Medical Charge, 5th Bombay Infantry, to the Medical Charge, vice Surgeon-Major Lyons, transferred permanently to the Civil Department. 5th Bombay Light Infantry: Surgeon-Lieutenant Kukday to the Officiating Medical Charge, vice Surgeon-Captain Jackson, appointed to the Medical Charge of the 2nd Bombay Lancers. Surgeon-Major Kirkpatrick, A.M.S., on arrival from England, has been posted to the Mhow District, and Surgeon-Major Culling, A.M.S., has been posted to the Bombay District. Brigade-Surgeon-Lieutenant-Colonel Salaman, Bombay Establishment, Superintendent Yerrowda Central Gaol, and Surgeon-Major Donald Frederick Dymott, Madras Establishment, 22nd Regiment of Madras Infantry, retire from the service.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Fleet-Surgeon M. F. Ryan to the *Howe*; Staff-Surgeon C. James to the *Eclipse*. Surgeons: Michael J. Smith to the *Jason*; A. X. Lavertine to the *Theseus*; R. Hardie to the *Eclipse*; C. G. Matthew to Chatham Hospital; and James P. Willis to the *Black Prince*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain A. A. Watson has been appointed Surgeon-Major.

VOLUNTEER CORPS.

Royal Engineers: 2nd Lancashire (The St. Helens): Surgeon-Lieutenant R. Jackson has been appointed Surgeon-Captain.

THE DONGOLA EXPEDITION.

We learn from Lord Cromer's report that the cost of Sir Herbert Kitchener's expedition to Dongola, including the money spent on railway and telegraph construction and on the purchase of gunboats, was £E715,066. His lordship gives a list of the details *seriatim*, but the only items which especially concern medical administration are "Medicines £E2498," and "Hospital rations £E797." The latter sum seems inadequate, but doubtless it was supplemented from other sources. Taking into consideration the magnitude of

Hosted by Google

the operations, the cholera outbreak, and the unavoidably heavy outlay on transport (coal alone runs away with £E37,895), it is clear, as Lord Cromer says, that a very effective control must have been exercised over the expenditure, more particularly as "there is no reason whatever to suppose that efficiency was in any way sacrificed for the sake of economy." The re-occupation of the province of Dongola has rendered the following additions to the Egyptian Army necessary: Three battalions of infantry, two squadrons of cavalry, a battery of artillery, and two companies of camel corps. This will of course lead to a considerable strengthening of the medical staff under Director General Gallwey, for in addition to military requirements the medical needs of the civil population of the re-conquered territory have to be provided for. The total losses of all kinds incurred by the Egyptian Army during the recent campaign are thus stated by Lord Cromer: Killed in action, 47; wounded, 122; died from cholera, 235; died from other diseases, 126. These figures refer to all ranks. Exclusive of cholera the sick-rate among the Soudanese and Egyptian troops was 3 per cent. In conclusion his lordship observes: "These statistics speak well for the general health of the force during an exceptionally severe summer. There can be no doubt that the Egyptian troops possess great powers of endurance and a remarkable capacity for hard and continuous work."

HEALTH OF THE BRITISH TROOPS IN INDIA.

Writing to the *Times* under date March 16th Colonel W. T. Dooner, replying to Captain Pirie, who suggests that the minimum age at which British soldiers are allowed to be sent to India should be raised by one or two years, says it is an error to suppose that the step suggested could be adopted without great difficulty and expense. Even under existing regulations—the *minimum* official age, as it may be called, being twenty—considerable difficulties frequently arise in finding the men for the necessary drafts. Were Captain Pirie's proposal adopted and the *minimum* age raised to twenty-two almost all men embarking for India would do so with only three years' unexpired colour-service. Instead of having to send out some 13,000 or 14,000 men per annum, we should have to send abroad yearly some 24,000, of course bringing back about a similar number. This would involve largely augmenting our trooping service, and a considerably increased charge to Indian funds and to the Army Estimates would be the result. If, however, our soldiers were treated as reasonable beings, and allowed after three years' service to draw their so-called deferred pay with their ordinary pay, it is possible, and highly probable, that a sufficient number of them would extend their colour-service to nine or ten years. The proposal would then be practicable.

FRENCH NAVAL STATISTICS.

The medical statistics of the French Navy are in future to be furnished according to a new system, which is fully explained in an article occupying the greater part of the *Archives de Médecine Navale et Coloniale* for February. In December, 1894, a new nomenclature of diseases was promulgated by the authorities, in which the various affections and accidents to which seafaring mankind is liable are set forth in seventeen sections under 275 heads. This document is to be strictly adhered to, the results being incorporated annually on a series of forms of which reduced specimens are given by our contemporary. Broadly speaking, the statistics referring to sailors and marines are to be kept separate, and reservists are not to be mixed up with men who are in their first period of service. The medical officer in charge of each unit is to supply information on six different forms, and also to send in a report of medical transactions somewhat similar to that in vogue with us. The information from hospitals is to be conveyed on four forms only, including one devoted to operations. For troops stationed in France the statistics should as far as possible refer to regiments or groups of battalions, but in the colonies it is of more importance to ascertain facts regarding stations.

TREATMENT OF PHLEGMONS.

According to a Russian military surgeon, Dr. Gueorguievsky, it is possible to disperse phlegmons and dry up purulent accumulations by the application of compresses steeped in a 2 per cent. solution of chemically pure bicarbonate of soda. The compresses, covered by some impermeable material, should be retained *in situ* under moderate pressure. The writer maintains that his method is vastly superior to all others, acting both rapidly and unfailingly. It is certainly a simple method enough, and as it cannot well do any harm may perhaps be worth a trial.

The Queen has granted Surgeon-Major Frederick Samuel Heuston, Army Medical Staff, authority to wear the insignia of the Imperial Order of the Double Dragon of the Third Class (third rank) which the Emperor of China has conferred upon him in recognition of his services to the wounded during the late war between China and Japan.

Correspondence.

"Audi alteram partem."

HOSPITAL ABUSE: THE LEEDS WORKPEOPLE'S HOSPITAL FUND.

To the Editors of THE LANCET.

SIRS,—May I be allowed to enter an energetic and emphatic protest against the misinterpretation to which my report on hospital abuse at Leeds has been subjected. An attempt has been made to twist what I wrote so that it should appear as if I thought that the workmen who subscribe to the Leeds Workpeople's Hospital Fund acquired by virtue of these subscriptions a right to be treated at the Leeds Infirmary; and, further, that it would be a good thing if this hospital were converted into a huge provident club. I meant and said nothing of the sort. On the contrary, I said the proposal to convert the infirmary into a provident club would be met "by the immediate resignation of the entire medical staff." Further, I stated that "it is denied that the workmen subscribers to the Workpeople's Hospital Fund have acquired the right to be treated at the infirmary," and this same assertion I repeat on two other occasions but in different phraseology. I quite agree with Dr. Eddison's remark, made at the recent annual meeting of subscribers, &c., of the infirmary, that "working people subscribed for the same reason as other people did—out of the kindness of their hearts and because they wanted to help." Such was the original motive that led to the creation of this fund; such, I hope, is still the motive of the majority of the subscribers. But it was not my mission to advocate any particular course of action or set of principles. I had to collect information without regard as to whether such information was agreeable or disagreeable to any particular party. Now the principal feature that disguished Leeds from the other towns I had visited was the admirable organisation, the power, and wealth of the Workpeople's Hospital Fund, and the fact that dissatisfaction existed which might lead to very serious consequences. One of the principal organisers of this fund met me with the assertion that "we were on the eve of a revolution." Surely it was my duty to describe the causes that gave rise to the existence in high quarters of such apprehensions.

An attempt has been made to deny the accuracy of the description I thus gave, which, it seems to me, tends, on the contrary, to confirm what I wrote. At the annual meeting of the Leeds Infirmary Mr. R. Benson Jowitt, treasurer and chairman of the board, is reported by the *Yorkshire Post* to have said that "he denied entirely that the demands from the Workpeople's Hospital Fund for rights—for value for their payments, for admission into the out-patients' room by virtue of their subscriptions—he denied that such existed except to the most limited extent." I described these demands, and it is now admitted that they do exist, but only "to the most limited extent." It would seem, however, that Mr. Jowitt was not satisfied with this sentence, for he immediately went on to qualify it in such a manner as would convey the impression that the demand was not, after all, so very limited. He said: "It was a danger they had thought of, spoken against, and guarded against from the onset. The meetings in connexion with the fund had *up to the last four or five months* been loyal, generous, and satisfactory, but since then there had been unwise and unguarded statements which had *caused such an article* to be written in THE LANCET which had done an *immense amount of harm*, and had given him and everyone connected with the infirmary a great deal of trouble. None of them desired to have any difficulty or rupture with the Workpeople's Hospital Fund, and yet to some people the

Hosted by Google

strain was becoming intolerable." The italics are mine; they serve to show that recently there have been difficulties of such a nature as to cause such an article as that which I had written and that the demands, far from being of "a most limited extent," had given rise to an immense amount of harm and produced a strain that was becoming intolerable. I fail to find anything in my report on the subject stronger or even as strong as this. The *Leeds Express* of March 11th, in a leader on Mr. Benson Jowitt's speech, confirms my view, for it holds that "there is no smoke without fire, and THE LANCET Commissioner did not evolve from his own imagination the complaints he set forth. Nor can it be overlooked that two of the Workpeople's Hospital Fund representatives on the infirmary board intimated, in speaking to resolutions adopted yesterday, that members of their fund had expressed dissatisfaction as to certain matters." The same paper adds: "It would be idle to deny, however, that the impression that people well able to pay for proper medical treatment have utilised the resources of the infirmary has caused considerable heartburnings among working-men subscribers. They do not begrudge the sums they contribute—sums which, though small, represent a certain amount of self-sacrifice; nor do they claim special and exceptional privileges. But they resent the idea that people far better able to contribute than themselves enjoy advantages of the institution without cost; while in some cases workmen who subscribe (even on a small scale) have not received quite the consideration or courtesy, as they think, that is desirable."

This is precisely one of the most important points I attempted to bring forward. I was dealing with hospital abuse. If there were no abuse the workmen subscribers would have no excuse for claiming rights. But it is natural that subscribers should complain if they are refused admission to the infirmary, when others who do not subscribe and are as well or better off than themselves are admitted. It is wrong of subscribers to claim the right of admission, but this wrong arises naturally out of another and greater wrong, the toleration of hospital abuse. Then it was also natural that, finding such abuse would not or could not be abolished, the suggestion should have gone forth of converting the infirmary into a provident club. I did not approve of this idea, but I recorded the fact that it existed. It would be a means of equalising conditions and of compelling those who do not subscribe to subscribe. Though there is a great deal to say against such a proposal it does seem to me quite natural that under actual circumstances it should have been made; but again I repeat that I did not mean to support in any way this solution of the difficulty. The *Yorkshire Post*, however, in its leader of March 11th, denies that help has been refused at the infirmary to those who pay in a regular and systematic manner, while it is freely given to those who do not pay at all, and declares that "such a state of affairs does not exist." I was told, on the contrary, that there had been a considerable amount of discussion concerning, for instance, the case of a very active committee-man of the Workpeople's Hospital Fund. In consequence of a fall this person suffered from some internal injury. His club doctor failed to effect a cure, and one day, when this committee-man brought to the hospital a sum of £7 odd which he had collected, he sought to obtain a second opinion from one of the surgeons on the infirmary staff. This advice was refused. Doubtless the refusal was, in one sense, quite justifiable; but the committee-man in question pointed out that many other patients were receiving advice who were in a better position than himself. Why, it was asked, should he pay and collect money for them when he could not get advice for himself. This is the sort of incident which occasions the present trouble, and that trouble is serious and may lead to very far-reaching consequences. Then, again, I am blamed for saying that the workmen "justly maintain that they do not receive from the infirmary anything like an equivalent for what they give to the infirmary." In the previous sentence I had mentioned that the cost of in-patients was £1 1*s.* 8½*d.*, and of out-patients 1*s.* 3¾*d.* per week. By this I did not mean that the workmen ought to receive an equivalent, but that their calculation was accurate when they said they said they did not receive an equivalent. Such a consideration is important, because if the present dissatisfaction were to greatly increase it might be financially possible for the workpeople to withdraw their subscriptions from the infirmary and establish a hospital of their own on provident lines. It is in view of this danger—doubtless very small at present, but which may grow—that the need of preventing the hospital abuse which engenders such ideas has become especially urgent. I endeavour to make my reports as free as possible from any sort of advocacy; but if I do advocate anything it is the prevention of hospital abuse. The virulent controversy that my remarks on the Leeds Workpeople's Fund has occasioned suggests that I succeeded in putting my finger on a sore place. The somewhat wild, impassioned, and contradictory manner in which attempts have been made to refute the description I gave of the grievance likewise suggests to my mind that that grievance is more serious and menacing than I had at first supposed.

I am, Sirs, yours faithfully,

March 16th, 1897. YOUR SPECIAL COMMISSIONER.

"THE MEDICAL STAFFS OF HOSPITALS AND HOSPITAL ABUSE."

To the Editors of THE LANCET.

SIRS,—Mr. Burdett's letter in THE LANCET of March 13th calls for a few remarks. First, with respect to a conference, Mr. Burdett is aware that my association proposed to hold one this summer, and that he wrote so strongly on the question that we thought it wise to postpone the question for a time. We are of opinion that the subject of hospital reform should be discussed not only from a *professional*, but from a *lay* point of view. It is perfectly true, as you have stated, that the medical and surgical staffs of hospitals are to a certain extent responsible for the present unsatisfactory condition of the out-patient department, but, on the other hand, the managing committees are surely the proper authorities to take the *initiative* in the work of reform. These committees must be aware of the crowds that attend the out-patient and casualty departments, and they must also be aware that their officials base their appeals to the public on the number of people who are thus attended. It is not improbable that representations on this subject have already been made by some of the staffs to the hospital authorities.

Mr. Burdett will, no doubt, be glad to hear that we are asking the Royal College of Physicians of London to make an investigation into the question. That College would be in a position to speak with *more* authority than any voluntary committee that might be formed in London. There appears to be one error in Mr. Burdett's letter. He states that Sir William Fergusson's committee recommended that medical officers attending the out-patients should be paid. I have carefully looked through the columns of THE LANCET, but I have failed to find this fact recorded. I believe some members of the committee did propose such a recommendation, but it was not agreed to. In conclusion, it will be gratifying to Mr. Burdett to know that we shall shortly publish the report of a sub-committee of our association which was asked to make an inquiry into the working of the special hospitals of the metropolis. As far as regards the general hospitals I believe I am not far wrong when I state that inquiries into the circumstances of patients are made at four only—viz., St. Bartholomew's Hospital, the London Hospital, the Great Northern Hospital, and the Royal Free Hospital, and that the number of *new* patients is limited at two only—viz., St. Thomas's Hospital and St. George's Hospital. St. Mary's Hospital has, as you probably are aware, recently appointed a special medical officer to sift the cases before they are seen by the assistant physicians and surgeons.

I am, Sirs, faithfully yours,
T. GARRETT HORDER,
Honorary Secretary to the Hospital Reform Association.

March 15th, 1897.

To the Editors of THE LANCET.

SIRS,—Mr. Burdett's letter is one of unusual importance to the profession. I venture, therefore, to suggest that every member of the profession should take an early opportunity of coming to your office to sign the petition to the Royal College of Physicians of London at present lying there. As we have no representative body who can undertake the consideration of the matter, the College of Physicians certainly appears to be the body who should undertake the duty of stating the case of the profession upon the matter of hospitals. Mr. Burdett is no doubt to some extent quite correct in attributing the present condition of affairs to the hospital staffs. The College of Physicians has the monopoly of hospital appointments in London upon the medical side,

Hosted by Google

and it is therefore not unreasonable to expect of that body something in return for that monopoly.

I am, Sirs, your obedient servant,

Hatfield, March 15th, 1897. LOVELL DRAGE.

"THE UNDIMINISHED MORTALITY FROM PUERPERAL FEVER IN ENGLAND AND WALES."

To the Editors of THE LANCET.

SIRS,—Dr. Rentoul endeavours to throw discredit on my statistics. It is one thing, however, to "challenge" statements; it is quite another to disprove them. The only point in his letter which even appears to justify his indictment is where he accuses me of not understanding the figures I am dealing with. If that were so it would, of course, seriously affect the value of my conclusions. But in the instance given it is Dr. Rentoul who has fallen into error. For although it is quite true, as he says, that where the death, from whatever cause, has taken place within a month of delivery the Registrar-General directs that this fact be mentioned in the certificate, it is equally true that in his returns the deaths *directly* connected with childbirth are placed in a separate table. Hence my statement is quite correct—viz., that deaths occurring from causes not directly connected with childbirth are, in the statistics from which I quote, left out of account.

Dr. Rentoul asks for "light" on the number of women who are ill in the hospitals but who do not die. So far as the General Lying-in Hospital is concerned, this information has been furnished in the most ample manner in a paper read before the Obstetrical Society by Dr. Boxall. It is also readily available with regard to all the more important continental lying-in hospitals.

Dr. Rentoul speaks of the statistics of the lying-in hospitals as fallacious, and in support of this allegation he refers to and repeats the statements he made on the subject before the Select Committee on the Registration of Midwives. Those statements have been refuted over and over again. The impression produced by Dr. Rentoul's evidence on the members of the Select Committee can be easily ascertained on reference to the Blue-book. On page 41 of the minutes of evidence it will be seen that towards the close of his long hearing Dr. Rentoul gave an answer that elicited the following remark from his questioner: "This is one of the many statements that you have made in the course of your evidence of a very grave nature which have been entirely unsupported by anything I could call evidence." After this estimate of his statements before the Committee it is surprising that Dr. Rentoul should dare to refer to them again.

Dr. Rentoul scoffs at antiseptics. Any man who can do this (I do not say any man who disbelieves in them, but any man who can scoff at them) in the face of the mass of evidence now available is beyond the reach of argument. There is such a thing as what my friend Sir William Roberts calls reason-blindness. Persons who suffer from this not very uncommon affliction are inaccessible to argument and impervious to the plainest facts. It does not make the least difference to Dr. Rentoul that his statements have been repeatedly disproved. Witness his often refuted blunder about one person in every fifteen dying in their first confinement. Here in his letter of to-day it crops up again, as though the statement had never been denied or even called in question.

I have no hope of being able either to convince Dr. Rentoul or to silence him. The object of my letter is simply to warn such of your readers as are not acquainted with his methods not to be misled by the sophistries with which his letter abounds.

I am, Sirs, yours sincerely,

CHAS. J. CULLINGWORTH.

Manchester-square, W., March 13th, 1897.

"A QUESTION FOR ANÆSTHETISTS."

To the Editors of THE LANCET.

SIRS,—Mr. Clement Lucas's question is one of transparent importance and may present the novelty to some which it appears to do to him. As a matter of fact, the danger of infection, and the manifestly filthy practice of using a blood-stained or vomit-polluted inhaler has appealed to me and, I should say, to all thoughtful anæsthetists for many years. The inhalers in common use—Clover's for ether and various forms of Junker's for chloroform—have been made so as to admit of absolute sterilisation. In the first case the face-piece can be constructed of celluloid or metal, either substance being capable of being made clean, and the more common leather and rubber face-piece is equally cleansable by water and carbolic acid. Mr. Lucas's suggestion with regard to the employment of toughened glass has been anticipated. I recently described such a face-piece, suggested originally by Vajna of Budapest, in the Year-book of Treatment, p. 171,[1] and drew emphatic attention to its value from the point of view of the surgeon who practises aseptic operations. Previously to this Mr. Krohne had made metal frames covered with domett or flannel, which were used with Junker's bottle and bellows. This face-piece can be boiled or baked, and by having two or three a freshly sterilised one can be employed for each case. As, then, the inhaler for ether made at my suggestion by Messrs. Mayer and Meltzer and the chloroform inhalers described above admit of the most rigid sterilisation, it can only be hoped that those who have not already realised the importance of Mr. Lucas's warning will do so and adopt the means already at hand for obviating the dangers which must follow the use of dirty inhalers. I do not suggest that the inhalers I have specified are the only ones which are clean, probably many others exist, nor do I enter upon the question whether or no pulmonary infection can occur from inhaling an anæsthetic from a dirty inhaler. It is sufficient that common sense and accumulated knowledge combine to warn us that danger must follow the use of filthy instruments, whether they be human hands, scalpels, or inhalers for anæsthetics. I may add that the anæsthetist and his clothing are possible sources of infection which should not be overlooked. Those whose lines fall among infectious or septic cases are not ideal anæsthetists from this point of view. Students who anæsthetise under my supervision are compelled to wear a clean linen coat and wash their hands and their apparatus before each case is commenced.—I am, Sirs, your obedient servant,

DUDLEY BUXTON, M.D., B.S Lond., M.R.C.P.,
Anæsthetist, University College Hospital.

Mortimer-street, W., March 17th, 1897.

"THE PROPOSED LEGISLATION FOR HABITUAL DRUNKARDS."

To the Editors of THE LANCET.

SIRS,—The Bill introduced last year into the Reichstag authorising the seclusion of habitual drunkards in separate asylums for drunkards not having yet been passed into law, the Landtag (Provincial Parliament) of Lower Austria, in accordance with a detailed report of Director Tilkowsky setting forth that there were in the five lunatic asylums in Lower Austria 107 suitable patients who might be at once transferred to a separate asylum for drunkards, has resolved in the session just closed to form a department for drunkards in an unoccupied portion of the penitentiary at Kornenburg, this resolution to take effect during the current year. How great a number of habitual drunkards are accommodated in the five lunatic asylums and penitentiary of Lower Austria may be gathered from statistics, which show that during the past ten years 2389 alcoholists have been received into the above-mentioned five lunatic asylums, and that during the last six years 1200 individuals morally ruined by habitual abuse of spirituous liquors have been provided for in the penitentiary at Kornenburg. The Provincial Parliament of Lower Austria, in a note urging the Government to pass the above-mentioned Bill, specially refers to the circumstance that Great Britain is at present occupied with the question of secluding habitual drunkards, and that the English Government, acting on a report of the departmental committee, has decided to extend and amend materially the provisions of the Habitual Drunkards Act. May a satisfactory result soon be arrived at by the English Parliament!

I am, Sirs, yours faithfully,

DR. FR. SCHLANGENHAUSEN.

Villach, Carinthia, March 13th, 1897.

"SHOULD EPILEPTICS MARRY?"

To the Editors of THE LANCET.

SIRS,—Professor Lankester is not satisfied with the instances I quote, thinking they depend on "the mere statements of patients." In Case No. 1 the son of the injured man was shown to me by the late Professor Rolleston, who had stated the case in his lectures on physiology. One eye was measured and found to be smaller than the other, and the sight of that eye was distinctly defective. As the father, in whom the corresponding eye had been injured, had been a friend of the Professor since childhood, when the injury took place, he had personally verified every particular. The facts are still clear in my memory, and are also fully stated in my notes of his lectures taken at the time. In the other cases I relied entirely on my own observation and the statements of medical men. Dr. Campbell explains such cases as instances of coincidence, and further suggests that the eyes may have been weak and the finger deformed before the accidents. Such, however, was not the case. I see no consistency in forcing the theory of coincidence to account for the inheritance of the results of lesions, while the entail of inherited deformities is admitted as "occurring in the usual way." It would take too much coincidence to explain away Dr. Brown-Séquard's guinea-pigs.

Dr. Campbell quotes the institutions for the blind where the inmates marry without fear. Would it not be more to the point if he produced the results of such marriages? My contention is still unanswered; I believe that there is evidence enough to prove that the results of lesions have been in many cases transmitted; that there is therefore in every case a considerable probability that such results will be transmitted; and further, that a large proportion of the accepted cases of heredity would, if it were possible to trace them, be found to have had their origin as the results of lesions. If that is not so, how does Dr. Campbell account for the origin of hereditary qualities?

In the matter of epilepsy, we find traumatism, syphilis, alcohol, and the thousand other causes producing the disease *de novo* daily. How can we avoid the conclusion that the hereditary cases arose in a similar manner? If they did not, then from what did they arise? Did the Creator plant a few original epileptics fully developed to disseminate the disease? It would be interesting to know if any observations have been made in the matter of the inequalities of limbs in subjects in the dissecting-room. Are these subjects, who come from a class eminently liable to accidents, more frequently asymmetrical than others, and, if so, to what extent? If my theory is correct I should expect a greater percentage of asymmetrical limbs in these subjects, and in any case I shall be glad to hear the evidence of those whose experience enables them to speak with authority. Meantime I submit that the science of heredity is not limited by "what is known and accepted" by Professor Lankester.

I am, Sirs, yours truly,

March 8th, 1897. W. G. THISTLE.

P.S.—The following is an extract from a letter just received from Mr. W. H. Jackson, M.A., F.R.S., Keble College, Oxford. "When Dr. Rolleston was at Pembroke he rowed in their eight. At a training breakfast one man threw half a loaf of bread at another crosswise along the table. The loaf took effect at the side of the temple, on which side I forget. The man who was struck slowly lost the sight of the eye on the side struck. In after life he was ordained and married. He had three or four sons, all of whom had the corresponding eye smaller than the other and with somewhat impaired sight. Rolleston said explicitly that from the inquiries he had made he did not believe there was any previous instance in either father's or mother's family of such a defect. Another of his stories was to the effect that an officer received a sabre wound across the forehead which healed leaving a very bad scar. Many years after he married: his firstborn, a son, showed a distinctly marked line across his forehead corresponding to his father's scar. There is not the least doubt that Rolleston was a firm believer that the effects of injuries are inheritable."

To the Editors of THE LANCET.

SIRS,—The correspondence on this subject which has been going on in the pages of THE LANCET since Jan. 23rd is of much interest to the profession and of importance to a not inconsiderable portion of the general public. I may therefore be permitted—without touching on the vexed question whether there is reason to believe that accidental lesions are transmissible from parent to offspring, and only as one who has had lengthened experience among the epileptic and the insane in some of our great metropolitan institutions—to add a few words to the discussion. It seems to me that in considering a question of the kind above noted an initial difficulty must always, more or less, present itself—that of determining with any degree of certainty from the history of the case and from the information vouchsafed by relatives or friends whether the epilepsy, be it "great" or "small," Jacksonian, or any other of the numerously described epileptic or epileptiform category, is solely and actually of lesion origin in any given case. It would, I think, be rash to accept such an assurance, not unfrequently made, without somewhat close investigation and examination. Every medical practitioner knows the difficulty there is in tracing heredity in disease accurately, even in the ordinary everyday maladies. There exists in the minds of patients and their friends the perhaps pardonable desire to attribute that which is due to undoubted heredity to some accidental cause. This difficulty is intensified a hundredfold when the malady happens to originate in the brain or nervous system. Hereditary tendency in such cases is not usually willingly acknowledged, endeavours to trace it are met by very circumstantial accounts of various injuries, and reasons are given, having the smallest foundation in fact, for the origin of mental defect and of maniacal or melancholic attacks; and perhaps in no form of cerebral disease is more ingenuity displayed than in accounting for the origin of epileptic fits. Injuries to the head or back, falls in infancy, gastric derangements, fear, sunstroke, *et sic de similibus*, play an important part when efforts are made to elucidate "causation" from the friends of the epileptic or insane.

Taking such circumstances into consideration, it would, I think, be unwise to counsel the confirmed epileptic, whatever the reported origin of the malady, to marry and to expect immunity in the offspring. Most of us who have been any length of time engaged among the insane know only too well how epilepsies and insanities are interchangeable and how one or the other may crop up, it may be quite unexpectedly, in different generations of the same family. These remarks apply, of course, only to true, well-recognised, and established epilepsy, with all its well-defined symptoms—a disease, however, which is perhaps more frequently simulated than any other. Some of apparently the most severe and violent cases of epilepsy which I have ever seen were undoubtedly due to hysteria. In one of them especially I remember the simulation was so perfect that I was for a moment deceived, the only fault in the performance being the issue of the scream at a period of the attack when there should have been, as was simulated, complete unconsciousness.

I am, Sirs, yours faithfully,

West Malling, March 6th, 1897. JAMES ADAM.

MECHANICAL IRRITATION OF SPECTACLES A POSSIBLE CAUSE OF FACIAL CONTORTIONS IN CHILDREN.

To the Editors of THE LANCET.

SIRS,—The origin of those facial contortions and spasms which are often seen persisting in some degree throughout life, and are singularly unpleasant to look upon, is often very obscure, and it seems, therefore, worth while to draw attention to anything that may throw light on it in some cases and lead to their being taken in hand before an incurable habit is established. About two years ago my attention was drawn to the spasmodic movements of the facial muscles in a small boy aged six and a half years who had been wearing spectacles for some time. The contortions had been noticed previously, but had got much worse lately, and involved nearly all the facial muscles. He had a marked rheumatic history and a mitral bruit, and at first I thought they were choreic, but a closer examination showed clearly that they were not and, further, that when slight they involved only the muscles at the root of the nose, the frontalis, corrugator supercilii, and pyramidalis nasi, radiating thence to the other muscles. It was also noticed that they were much worse when he wore his spectacles, which he had been ordered to do constantly for myopic astigmatism. No fault could be found with the glasses either optically or

Hosted by Google

mechanically, but it struck me that possibly the mere mechanical irritation of the frame in a very neurotic child might suffice. I therefore reluctantly ordered the glasses to be given up for a time, as there seemed every chance of an irremediable habit being established. He accordingly dropped their use entirely for some months with the result that the facial contortions ceased entirely except when the spectacles were put on again experimentally. I have just heard that they still return when he wears his glasses (which he does for near work), though not so badly as before. I was able to watch the boy closely myself, and I think there can be no doubt about the sequence of cause and effect in this case; it makes a very awkward dilemma where the defect of vision is a serious one, but a good deal has to be sacrificed to prevent the establishment of a habit which in after years is probably incurable, is very unpleasant to the patient's friends, and annoying to himself.

I am, Sirs, yours faithfully,
E. HOBHOUSE, M.D. Oxon., M.R.C.P. Lond.

Brighton, March 14th.

THE CONSTITUTION OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—Some little time ago the Council of the Royal College of Surgeons of England framed a series of regulations under which meetings of Members might be held at the College. The chief of these regulations are: 1. These meetings will be for consultative purposes only, and can have no official or corporate character or efficacy. 2. Meetings shall be summoned by the Council at such times and for such objects as may by the Council be thought desirable either with or without a requisition from the Members. 3. Such requisition must be signed by at least thirty Members and contain a statement of the objects for which the meeting is requested.

No meeting has hitherto been called under these regulations, but the committee of the Society of Members, in view of the unfavourable circumstances surrounding the recent poll of the Fellows, decided to apply for such a meeting. Accordingly, the following requisition was drawn up and signed by thirty Members:—

"*To the President and Council of the Royal College of Surgeons of England.*

"GENTLEMEN,—We, the undersigned Members of the College, hereby very respectfully request you to call a meeting of Members at an early date, in accordance with your regulations, in order that the Members may have an opportunity of consulting together upon the following matters:—1. The results and validity of the recent poll of the Fellows. 2. A proposal urging the Council to take a similar poll of the Members on the question of representation. 3. The validity of the present mode of appointment of the representative of the College on the General Medical Council. 4. The refusal of the Council to carry out the by-laws of the College in the case of Mr. R. B. Anderson. Motions on these subjects will be submitted on receipt of information that the meeting will be held."

This requisition came before the Council on Thursday last and was refused, the secretary being instructed to state "that the Council does not think it desirable that such a meeting should be held."

Now, Sirs, while I fully admit that the refusal of a meeting is within the discretion of the Council under the above regulations, I venture to think that the Council has made a mistake in so acting on this occasion. If a temperately worded request stating objects which are recognised as reasonable and important by many Members of the College is to be refused simply because the majority of the Council does not agree with these objects, then I submit that the regulations are absurd and had better be rescinded in so far as they relate to meetings called by Members, since they will never be acted upon. Further, the result of this attempt to stifle discussion within the College must certainly be to drive the Members into acts of open hostility without its walls. There are frequent occasions when, in spite of its claim to be "a purely scientific body," the Council is brought into contact with "the State, the profession, and the public." One of these arose two years ago in connexion with the amended by-laws, when the result of the Members' interposition was that the Home Secretary refused to sanction the by-laws in the form desired by the Council. A conflict of opinion has now occurred between the Council and another department of the Government, and if the Members are again found in the enemy's camp is it to be wondered at since they are so persistently turned out of their own? The result in this case will be more serious to the College than in the last, and the Members, who have the welfare of the institution as much at heart as the Council, would be gladly spared any intervention. The obstinate refusal of the Council, backed up by a *minority* of the Fellows, to grant the Members a share in the management of what is by charter their own property leaves the latter, however, no alternative but opposition at any and every opportunity.

I am, Sirs, faithfully yours,
March 15th, 1897. W. G. DICKINSON.

EXCISION OF THE KNEE-JOINT.

To the Editors of THE LANCET.

SIRS,—I have been interested in reading Mr. C. B. Lockwood's paper entitled "A Review of the Operation for Excision of the Knee, together with an Account of a New Procedure—Osteoplastic Excision of the Knee." It is, I believe, quite twenty years since Dr. Fenwick of Montreal was in Liverpool and showed us photographs of a large number of cases in which he had excised the joint, using his curved section of the bone. The results were excellent, and I adopted his method as soon as I obtained a hospital appointment; but very shortly changed it for a wedge-shaped section, which I have carried out for at least fifteen years. The wedge is not cut in the same way or based on the same principles as those advocated by Mr. Lockwood, but attains, I think, at least equally good results. The femur is cut into a wedge by removing slices from the condyles anteriorly and posteriorly, which include the whole of the articular cartilage, but leave the epiphyseal cartilage intact. A corresponding notch in the head of the tibia also removes all the articular cartilage with a very small portion out of the centre of the epiphyseal cartilage. The nature of the wedge of course renders antero-posterior displacement and rotation out of the question, and usually so firmly locks the bones that a special splint is unnecessary. I fail to see the particular importance in retaining the ligaments when the operation temporarily fixes the parts and the subsequent ankylosis renders them unnecessary; but, of course, the retention of the muscular attachments is a different matter, and I agree with Mr. Lockwood that the continuity of the extensor tendon with its insertion through the ligamentum patellæ should be restored as perfectly as possible.

I am, Sirs, yours faithfully,
Liverpool, March 15th, 1897. F. T. PAUL.

"THE ETIOLOGY OF BERI-BERI."

To the Editors of THE LANCET.

SIRS,—I observe in THE LANCET of March 6th a letter from Mr. J. Tertius Clarke with reference to the epidemics of beri-beri in this asylum, suggesting that the outbreaks were due possibly to tin poisoning. I do not see how this could have been the case, as the water-pipes are of iron and the ordinary amalgam used for such purpose throughout the city. Cooking utensils are not tin-lined either, and, generally speaking, this metal is very little used in the institution. It would be of interest to know if Mr. Clarke's patients have been living in the neighbourhood of a tin-producing district.

I am, Sirs, yours truly,
J. O'CONOR DONELAN,
Acting Medical Superintendent, Richmond Asylum.
Dublin, March 11th, 1897.

"A SUCCESSFUL SOCIETY!!"

To the Editors of THE LANCET.

SIRS,—In an annotation in THE LANCET of March 13th dealing with my letter to the Prince of Wales on the subject of vivisection you say that to cut up animals alive without the pretence of anæsthetics in the laboratories attached to the London hospitals would be a wholly illegal proceeding, and you ask why we, who would protect animals from torture, do not attempt to get those who do these illegal acts convicted. My answer is that these acts, unfortunately, are not illegal. You must surely be perfectly well aware that attached to these laboratories are persons holding licences that exempt them from the necessity of using any anæsthetics whatever; and my legal training, to which you are good enough to

Hosted by Google

allude, does not lead me to blame the anti-vivisection societies for not instituting prosecutions in these circumstances.

You seem to wish people to believe that animals are not cut up alive without anæsthetics in these laboratories, but before you can succeed in this it will be necessary for you to explain why all these vivisectors are at the pains to obtain licences year after year exempting them from the obligation to use anæsthetics. According to the last Home Office report no less than thirty persons on the staffs of the London hospitals held these licences. Perhaps if there were fewer such vivisectors connected with these hospitals there would be more subscribers.

I am, Sirs, your obedient servant,

STEPHEN COLERIDGE.

Egerton Mansions, South Kensington, March 14th, 1897.

*** It has been stated again and again, and is a fact within our own knowledge, that the only experiments performed without anæsthetics are inoculations and hypodermic injections. How can Mr. Coleridge justify the use of the words "cut up alive" as describing such proceedings?—ED. L.

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—As a practitioner of over twenty years' standing I should like to express my approval of Mr. Flemming's letter in THE LANCET of March 6th. Surely there is another view than the selfish dread of the imperilling of our own interests. I have seen a good deal of the work of the women who attend the labours of the poor, and their ignorance of the simplest matters has lost all novelty to me. I have seen a huge abscess produced in the breast of a newborn baby through the midwife's having conscientiously done her duty in "breaking the baby's breast-strings"—a process of kneading and pinching. I have been called to a woman to find that a blue hand had been protruding from her vulva for hours, while the midwife exhorted the bystanders to wait and give nature a chance, until they took matters into their own hands and sent for me. I have been called to find a woman lying dead with the funis pulled away and the placenta still in the uterus, and absolutely within a fortnight to another case where the same midwife had pulled away another funis, and the hæmorrhage was most alarming. In reference to these two cases I asked a magistrate if a warning could not be issued to the woman. His reply showed a callousness worthy of a Turk. "If they will employ such women they must take the consequences." I say they must employ these women, and they must *not* take the consequences. There must be no consequences. No woman should be allowed to attend a case who is capable of pulling away a funis and taking no steps to remedy the disaster. A few months ago I got an urgent message to see a woman. I galloped the three miles to her house and found her dead. The midwife explained that she had bled a good deal, but as she always bled a good deal it had occasioned no alarm. Think of it! The poor creature's life had not only been risked at every confinement, but her convalescence unduly prolonged owing to the exhaustive loss. It is easy to realise the suffering in the case of a labourer's wife, who has to attend soon to her household duties. It is useless to argue that these people should pay a medical man. They cannot do it, and they only deserve credit for not employing him and leaving him unpaid. In this case the midwife was known to me as a favourable specimen of her class—clean, kind, and attentive according to her lights. No inquest was held, as the police informed the coroner that she had done her best. Now, ought any midwife's best to be like that?

I am, Sirs, yours truly.

March 15th, 1897. FOR REGISTRATION.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Corporation Bill; Withdrawal of the Conduit Scheme.

IT is stated that the clause in the Corporation Bill being promoted this session, authorising the construction of a conduit about nine and a half miles in length, to carry the effluent from the sewage works at Davyhulme into the Mersey near Thelwall, has been withdrawn. Strong opposition was given to the scheme at a town's meeting held last week, and on the question being put there was a majority against the retention of the clause. Alderman J. Thompson, chairman of the rivers committee, formally demanded a poll; but at a meeting of the committee which has since been held it was decided to give up the poll and to abandon for the present the attempt to obtain power for the construction of the conduit, though the committee and the surveyor are still said to think that this scheme, estimated to cost over £200,000, will probably prove the best way out of the sewage difficulty. The subject is surrounded with difficulties. The Local Government Board gives no help in surmounting them. It is almost impossible to obtain land for filtration, and its cost is extravagant, while it is said that all chemical methods of dealing with the sewage have failed in producing an effluent satisfactory to the Mersey and Irwell Committee. But the resources of science ought not to be as yet considered exhausted.

Trafford Park.

Trafford Park, which for nearly 900 years has been in the continuous possession of the De Traffords, and has for ages been a health-giving open space, to the incalculable benefit of Manchester and Salford, while they have been growing century after century more dingy, more smoky, and more crowded, is now about to be "developed." In the words of an interviewer, this means "the conversion of the ancient and beautiful demesne of the De Traffords, with its pretty groves, its rich verdure, and its playful deer, into a hive of industry—a place of ironworks, cotton mills, malting houses, and the like. The old baronial hall is to become a grand hotel." Of the 1183 acres of which it consists about 100 acres, skirting the Ship Canal for something like two and a half miles as a strip from 100 to 120 yards wide, will be reserved for dock wharves and terminals for the lines to be connected with the Manchester dock railways. Mr. Marshall Stevens, who has transferred his energies from the Ship Canal to the syndicate and now acts as Mr. Hooley's right-hand man, says that for some "slices" no less than £5000 per acre have been recently bid. What this means from the hygienic standpoint is pretty clear. Much room for fresh air cannot be given at £5000 per acre. Mr. Stevens speaks cheerfully of works for the distillation of tar, for the preparation of a patent fuel (which is to be an important industry), saw mills, flour mills, cotton and seed-crushing mills, oil tanks, malting houses, a ship-building yard, and dry docks. About 750 acres are set apart for these purposes. A central space of about 200 acres is to be reserved as a race-course or public park. The hall and adjoining buildings are to be "converted into a first-class hotel, the gardens and a portion of the park being reserved for golf links and a recreation ground." Railway lines are to bring all the mills and manufactories built into connexion with the Dock Railway and the whole railway system of the country. Having thus provided a delightful fringe of nuisances—for it must be remembered that the Bridgewater Canal skirts a considerable extent of the park and will contribute its quota towards the creation of this earthly paradise—Mr. Stevens says with charming humour: "Doubtless villadom will seize upon certain sections of the estate, for portions of the park rise well above the level meadows; and here you will virtually be able to live in the country and yet be in closest touch with the city." And so the dream in which many indulged of a noble park to be held for ever in trust for the thousands of workers and their children who can rarely or never get beyond the sight of the city chimneys comes to an end. Surely the City Fathers must be conscious of the fatuity and ineptitude which allowed others to forestall them, while they were giving the question of purchase "their best consideration."

March 16th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

"Army Doctors."

PARAGRAPHS have recently appeared under this heading in the *Newcastle Daily Chronicle*, calling attention to the difficulty the authorities are experiencing in filling vacancies in the Army Medical Department, and stating that the difficulty is due to the circumstance that the medical officers

Hosted by Google

do not enjoy military rank, and are not in the English, as in the Continental armies, addressed as major or colonel, &c., as the case may be, but as "doctor." Possibly this explanation represents the popular view, but surely the position held by Army medical officers ought to depend on the fact that their duties are essential to the welfare of the troops and not on any other consideration.

Death of Mr. W. Boyd, Surgeon, of Durham.

Mr. Boyd has just died at Durham, aged seventy-nine years. He had been elected Mayor of Durham on four occasions, and seven years ago the freedom of the city and his portrait, which now hangs in the town hall, were presented to him. He was the oldest medical practitioner in the city of Durham and was described as the father of the town council.

The Medical Officer of Health for Northumberland.

At the statutory March meeting of the Northumberland County Council it was resolved that Dr. Hembrough, whose term of office as medical officer of health for Northumberland would expire next May, should be appointed permanently.

Durham County Hospital.

By the death of Mrs. Elizabeth Snowball, which occurred last week, the funds of the Durham County Hospital will benefit to the extent of £6000.

March 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Chair of Medical Jurisprudence in the University of Edinburgh.

ON the recommendation of the Secretary for Scotland Sir Henry D. Littlejohn, M.D. Edin., has been appointed to this chair. It has been arranged that in the meanwhile, until time has been given for other arrangements to be made, he will also teach public health. Sir Henry Littlejohn graduated in medicine at the University of Edinburgh in 1847. He has for many years been a lecturer in the extra-mural school of medicine on the subjects he is now called upon to teach within the walls of the University. He is also well known in Scotland as an expert medical jurist. He is a man of much vigour and unusual activity for his years, and has been a popular teacher, a popularity he will doubtless retain in his new position.

Honorary Degrees at the University of Edinburgh.

It is intimated that the University has offered the degree of LL.D. to Professor Sir Douglas Maclagan and Dr. John Wyllie. The former has been referred to here at the time of his retirement from the chair of Medical Jurisprudence. It is generally felt that the tribute to Dr. Wyllie, on his retirement from the staff of the Royal Infirmary, is a very suitable one and fully deserved.

The Edinburgh Royal Medical Society.

The annual dinner of this society was held last week. Professor Burdon Sanderson was the guest of the evening, and in replying to the toast of his health spoke of the advances in medicine since he studied in Edinburgh.

Close of the Winter Session at the University of Edinburgh.

The winter session in the Faculty of Medicine terminates this week.

Glasgow Royal Infirmary.

It is now practically decided that the tribute Glasgow will offer in celebration of the Queen's long reign is to be the extension and improvement of the Royal Infirmary. At a meeting of the citizens on the 12th inst., after a loyal address of congratulation to Her Majesty had been adopted, Sir John Muir moved a resolution in favour of the proposal to raise a sum of money for the purpose of re-constructing the older portion of the Royal Infirmary. This was seconded by the Lord Dean of Guild and supported by the Rev. Dr. Marshall Lang. Thereafter, on the question being thrown open to discussion, though the general voice was in favour of the proposal as submitted, there were not wanting supporters of the alternative proposal put forward in THE LANCET—viz., that the infirmary be re-built on a new site. Mr. Quarrier and Dr. McGregor Robertson both urged the unsuitableness of the present situation and the difficulty or impossibility of so altering the present building as to produce a really satisfactory hospital. To all this, however, the Lord Provost turned a deaf ear. He evidently had made up his mind in favour of the scheme for altering the building on the present site, and would have no other. His position, he maintained, rested on the reports of medical, surgical, and sanitary experts, and he objected strongly to the removal of the infirmary on the ground that to do so would make it of less value in relieving men injured by accidents in the neighbouring works. Under these circumstances the critics of the official scheme did not see their way to submit an amendment, and the resolution was accordingly carried unanimously. The Lord Provost then intimated the following subscriptions: Sir John Muir, £5000; A Friend, who preferred to conceal his name, £5000; Sir James Bain, £1000; Sir James Tring, £1000; Mr. John S. Templeton, £1000; Mr. Hugh Brown, chairman of the infirmary, £500. Whatever differences of opinion may exist on points of detail there is a universal desire both for the sake of the hospital and in honour of the occasion to make the movement a magnificent success. The anxiety of at least a section of the public and the profession in reference to the present site and the reconstruction scheme has certainly some basis, and it is not unreasonable to ask that the names of the medical, surgical, and sanitary authorities upon whose advice the official scheme is based should be published. It is only right that the public who are asked to contribute the funds shall be placed in a position to determine whether the guarantee that the money will be rightly expended is or is not adequate. There is no word of controversy concerning the decision to help the Royal Infirmary. But there are in many quarters reasonable questionings as to whether the official proposal embodies the best possible plan, and it will be to the interest of the authorities to meet this position by a frank statement of the sources of the advice upon which their decision has been taken.

University of Glasgow.

The University Court have granted leave of absence to Dr. P. A. Simpson, Professor of Forensic Medicine, on the ground of ill-health. Mr. Hugh Galt, M.B., C.M. Glasg., D.P.H. Camb., has been appointed to act as Lecturer and Examiner in Professor Simpson's absence. The Court have agreed to recognise attendance at the wards and dispensary of the Glasgow Eye Infirmary for the purpose of graduation in medicine under the new ordinances. The classes in Forensic Medicine and Public Health and in Practical Pathology at St. Mary's Hospital Medical School, Paddington, have also been recognised by the Court. The Students' Medico-Chirurgical Society have elected Professor John Yule Mackay to the position of Honorary President, Mr. Wm. Duncan, M.A., being appointed President. The winter session in the Faculty of Medicine is to close on the 19th inst.; in the other faculties the classes are continued into the following week.

Proposed Memorial to William and John Hunter.

The Faculty of Physicians and Surgeons of Glasgow have brought their proposal to establish a local memorial in honour of William and John Hunter, the brothers being natives of Lanarkshire, before the town council, and a small committee of the council, including the Lord Provost, has been appointed to act with the Faculty.

University College, Dundee.

At a recent meeting of the council of the College Dr. John Yule Mackay, Professor of Anatomy, was unanimously appointed Principal of the College. The new Principal is a graduate in medicine at the University of Glasgow, where for twelve years he occupied the position of senior demonstrator in anatomy and was also lecturer on embryology. Some ten years ago he was appointed to the chair of anatomy in Dundee. He is joint author with Professor Cleland of a recently published work on human anatomy, and has conducted a number of original researches, the most important being those dealing with the development of the heart and blood vessels.

Deaf-Mutism and its Prevention.

Dr. James Kerr Love of Glasgow read a paper on this subject before the Royal Society of Edinburgh on the 15th inst. Amongst the propositions advanced were the following: (1) that congenital deafness is hereditary; (2) the tendency to have deaf progeny was the same whether one or both parents be congenitally deaf; (3) the hearing brothers and sisters of the congenital deaf-mute are as liable, if they marry, to have deaf progeny as the deaf themselves; and (4) consanguinity of the parents emphasises the

Hosted by Google

hereditary tendency in the offspring, and in this way many cases of congenital deafness arise. In dealing with suggestions for prevention Dr. Love remarked that this aspect of the question was dominated by the fact that the tendency was a family one, and that nothing short of repressive measures was therefore likely to be successful. He advocated the appointment of a Commission to inquire into the whole subject.

March 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Accidental Poisoning by Arsenic.

ANOTHER case of accidental poisoning has just occurred in Dublin, in which some carelessness was fairly attributed by the verdict of the coroner's jury to the manufacturers of a special sort of rat poison. The facts were shortly as follows. A boy named Hardman obtained a package of cakes labeled "Hammond's Patent Rat Poison," and used some of them on three occasions for poisoning rats. One day he carelessly left a portion of a cake in his topcoat pocket before going to school. Some three of his schoolfellows subsequently obtained possession of it and ate it, with the result that all three suffered from symptoms of irritant poisoning, while the boy George Taaffe, aged ten years, died in about twelve hours. It appeared at the inquest on the 15th that the cakes resembled common meal cakes, and that there was nothing, in the absence of the special wrapper, to warn people that they were poisonous. The manufacturers of the patent poison were communicated with by telegraph and stated that its chief ingredient was arsenic. The jury found that the deceased died from accidentally eating Hammond's Rat-cake Poison, and they condemned the shape of the cakes as sold to the public, inasmuch as they resembled common brown cakes.

Death of Surgeon Thomas Gibbons, R.N.

Surgeon Thomas Gibbons, whose tragic death by drowning took place in Kingstown harbour on the 14th inst., was a graduate of Dublin University, where he obtained his medical degrees in 1892, and was only twenty-seven years of age. The deceased, accompanied by Lieutenant Ellison and two other officers of H.M.S. *Jason*, reached Kingstown from Dublin by the last train on Saturday night and hired a boat to put them on board their vessel. It was a perfectly calm night, but, as appeared at the inquest, the boat filled and foundered in mid-harbour, leaving its six occupants struggling in the water. Sad to say, Surgeon Gibbons and the two boatmen were drowned. An ominous circumstance overshadows this lamentable fatality in the fact that some years ago two brothers of the deceased boatmen lost their lives while rowing some bluejackets of H.M.S. *Belleisle* to their ship. Something happened to their boat, and they also were drowned in the harbour. It would seem time that some superintendence should be exercised by the proper authorities over boats which ply for hire at Kingstown, especially in reference to punts permitted to carry six men.

The Union Hospital, Belfast.

The following report has been made on the Belfast Union Hospital by Mr. Agnew, the Local Government Board inspector: "This hospital is in charge of a visiting and resident medical officer. There were ninety-one cases on the date of my inspection; the nursing staff consists of a superintendent, four day nurses, and three night nurses, all trained and efficient. This building, including about £4500 spent on it in recent years, has cost almost £30,000. This hospital, with its highly efficient nursing and medical staff, is admirably suited for the treatment of infectious cases. The wards are bright, cheery, clean, and well ventilated. The beds are comfortable, bedclothes clean and sufficient, dietary ample and suitable. The patients are well attended to. Most respectable people from Belfast and neighbourhood come to this hospital, as it is the only one in the city which possesses anything approaching the requirements of a fever hospital."

Sir W. Mac Cormac and Queen's College, Belfast.

On the afternoon of March 15th, in the presence of a large company, Sir W. Mac Cormac was paid a high compliment in the library of Queen's College, Belfast, his native city. When he was made President of the Royal College of Surgeons of England it was decided by his fellow graduates and friends that the time was come to do him some honour, and it was decided that the presentation of his picture should be made. This has been painted by Mr. Harris Brown, and has been handed over by the recipient to the authorities of Queen's College, Belfast. The President of Queen's College, who occupied the chair, having opened the proceedings, the Marquis of Dufferin and Ava, who was chairman of the Portrait Committee, in unveiling the picture, made one of those neat, diplomatic, and complimentary speeches for which he is so famous, and referred in very happy terms to Sir William Mac Cormac's distinguished career which had culminated in his election to the high office of President of the Royal College of Surgeons of England. Sir William Mac Cormac made a feeling reply, in which he briefly traced his career, and pointed out that he was, he believed, the only Irishman not educated at a London school who had ever attained to the position of President of the Royal College of Surgeons of England. The portrait represents the distinguished surgeon in his official robes. In the evening Sir William Mac Cormac was entertained to a banquet (held in Queen's College) by the members of the medical profession in Belfast. About seventy gentlemen sat down to dinner, among them being a considerable number of guests, the President of Queen's College, the Lord Mayor of Belfast, Sir W. Stokes (Dublin), Sir James Musgrave, B.Lit., D.L., Sir W. McCammond, and a number of the professors of the Arts Faculty. Professor Cuming occupied the chair; and the President proposed the following toasts: "The Queen," "The Prince of Wales and other Members of the Royal Family," and "The Lord-Lieutenant and Prosperity to Ireland" (to which the Lord Mayor of Belfast responded). In giving the toast of "Our Guest," Professor Cuming spoke in complimentary terms of Sir W. Mac Cormac's career from the time he was a student, an undergraduate of that College, until now. Sir William Mac Cormac very happily replied. The next toast, "Queen's College, Belfast," was proposed by Sir W. Stokes (Dublin), and to this the President of Queen's College replied. The last toast, "The Chairman," was proposed by Sir W. Mac Cormac, and Professor Cuming responded. Dr. McKisack and Dr. John Campbell were secretaries of the banquet and to them largely its success was due.

Sad Death of a Medical Man.

Some years ago Mrs. Riordan instituted proceedings against her husband, Mr. Riordan, medical officer of the Cloyne Dispensary District, for the purpose of procuring a judicial separation. He entered a counter-plea charging her with adultery. The jury exonerated Mrs. Riordan and the Court decided that her husband should provide her with separate maintenance. Lately, owing to some complaints as to the manner in which Mr. Riordan had discharged his duties, the Local Government Board called on him to resign his position as dispensary medical officer. This fact and the conviction that he had made an unfounded accusation against his wife preyed very much on his mind, and he endeavoured to make reparation to her by handing over the title deeds of some property he held to her solicitor for the purpose of having the property conveyed to her. He died very suddenly on the 16th ult., and as there were rumours in the locality that he had committed suicide by poisoning the coroner considered it prudent to hold an inquest last Wednesday. The evidence of his daughter was most pathetic. She stated that he was constantly expressing sorrow for the accusations he had made against her mother. Describing his final illness, which occurred at the breakfast-table, she said: "Whilst speaking to him I noticed that his eyes were getting dilated and he stared at me. After taking a mouthful of bread and tea, he looked at me again and said to me, 'Don't get excited.' He moved then towards the end of the table and came back again. I said, 'My God, you are dying. Tell me what is up with you, Father.' He said, 'There is nothing the matter with me.' I then put my arms around him, crying, when he said, 'Don't fret; it is apoplexy.'" The jury brought in a verdict of death the result of apoplexy, and expressed their most sincere condolence with the relatives of the deceased gentleman.

March 17th.

FOOTBALL CASUALTY.—During a match on the 10th inst. at Reading, between Woolwich Arsenal and Reading, the captain of the visitors' team fractured a bone of his left hand.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Libel on the Memory of the late Professor Dolbeau.

THE family of Dr. Dolbeau, Professor of Surgery at the Academy of Medicine, who died some years ago, has just been successfully engaged in a very curious lawsuit. The appellants were anxious to obtain an injunction against a book published by M. Lissagaray dealing with the Commune in 1871. In this book the writer, himself an old Communist, accused Professor Dolbeau of having committed a grave offence against professional honour. He alleged that in 1871, when Dr. Dolbeau was surgeon-in-chief to the hospital at Beaujon, some wounded Communists who were in his wards were handed over by him to the police and accordingly shot. This story, which was spread abroad during the life of Dr. Dolbeau, naturally gave rise to a grave feeling against him. The students who attended his lectures hissed him, and he died a short time afterwards through worry and mortification at the hostility shown towards him. The real truth of the matter, as has been shown in the recent suit, is that in exact opposition to the allegations Dr. Dolbeau did his best to save the wounded Communists, and when they were convalescent tried to send them out of hospital under false names. Unfortunately, Dr. Dolbeau forgot the names agreed upon (or, rather, never knew them), and when the discharge-sheets were presented for signature a policeman who was there saw through the unskilful ruse and arrested three men. They were not, however, shot. These facts were established some years ago, and the children of Dr. Dolbeau now sought an injunction against M. Lissagaray's book, so as to have an official denial of the accusation which weighed so heavily on their father's memory. The court granted the injunction applied for.

The Plague.

A recent enactment of the Minister of the Interior annuls the decree of Feb. 9th, which prohibited the entry of vessels coming from India into the port of Marseilles. The new order establishes one uniform regulation for all French ports, the organisation costing 247,000 francs. The Minister also asks the Chamber for an additional sum of 150,000 francs to complete a sanitary installation at Marseilles. The prohibitory measures in force at this town with regard to goods coming from Bombay have given rise to a lawsuit between two large firms, of which the import house was unable to meet its engagements for the delivery of some oil-bearing seeds. The commercial courts decided that the decrees of prohibition constituted a case of *force majeure*, an accidental circumstance quite independent of the wishes of the importers, who could not be held responsible, and that therefore the contract lapsed without any damages. The Correctional Court of St. Malo has just condemned a captain who had made a false sanitary declaration at St. Pierre and Miquelon to eight days' imprisonment and a fine of 16 francs.

The Sanitary Service for the Paris Exhibition of 1900.

The organisation of this service has just been arranged in a most precise fashion and the works have already begun. The plan for a hospital to be built in the centre of the exhibition has been rejected. This idea was the suggestion of M. Marcel Baudouin, who had seen a similar establishment working at the Chicago Exhibition. But at Chicago the exhibition buildings were outside the town, far away from the hospitals, and the transport of the wounded or sick for so long a distance would have been both difficult and dangerous. At Paris, although the exhibition buildings cover an immense area, they are close to the populous quarters where hospitals abound; in fact, there are five of which the most distant is not more than ten minutes away from the centre of the exhibition. The ambulance service for the transport of the sick and wounded can therefore meet every want without incurring the enormous expense of the construction of a temporary hospital. At the head of the new service is Dr. Gilles de la Tourette, who has appointed fifty assistant surgeons to aid him, who will be drafted to different relief stations, where one or two will be always on duty. To particularise some other measures, all workmen who have not been vaccinated or re-vaccinated within the last two years will be gratuitously vaccinated at any medical station; exhibitors, their employés, or workmen, and all visitors wounded or stricken with sickness inside the buildings will receive first aid at the medical stations on application, or, if necessary, will be conveyed thither by the administration. For every sick or wounded person thus treated the medical staff will take a ticket and issue a special bulletin. The expenses of drugs, dressings, &c., will be defrayed by a special fund supplied by a rate of 1 per cent. on any contracts which the administration makes with contractors or exhibitors. If at the close of the exhibition there be any money over from this fund it will be handed to the Assistance Publique; if, on the contrary, the fund is found to be in debt the general fund of the exhibition will pay. The surgeons employed by this service will receive ten francs for every time they attend at the buildings. Despite the smallness of the fees, the applications to take part in the work are innumerable and include the well-known names of several hospital surgeons.

The Pharmacopœia.

The Minister-in-Charge has appointed a Commission to revise the Pharmacopœia, the use of which is obligatory on all druggists, and a revision of which is made about every ten years.

Horses at the Pasteur Institute.

It is well known that for the preparation of the various serums at the Pasteur Institute, and for the preparation of anti-diphtheritic serum particularly, there is at Garches a large stable capable of accommodating eighty horses. At first it was impossible to pick these animals with much care for want of funds. At present, since it has been shown that the state of health of the horse exercises a great influence upon the value of the serum, and more especially upon the accidents which may arise from its use, the horses have been selected with the greatest care. A recent bequest of two million francs from Baron Hirsch to the Institute has been the means of allowing large sums to be expended on the purchase of horses and so of improving the quality of the serum. Among these horses are many with a notable past, and I may mention the charger of Marshal Canrobert and Saint Claude, formerly a steeplechaser belonging to Baron Finot, and the winner in 1890 of the great hurdle race at Auteuil.

Banquet to Madame Clémence Royer.

A great banquet has been held at the Grand Hotel in honour of Madame Clémence Royer, who translated Darwin's works, and has always been a great promoter of the evolutionary movement in science. She recently attained her seventieth birthday, and has devoted her whole life to metaphysical biology. Always struggling with undaunted energy, suspected on account both of her Chauvinist proclivities and her sex, and receiving neither encouragement nor reward, she has now reached old age, without fortune or honours, in the Hospice Galignani. The banquet was attended by the *élite* of the scientific world at Paris, and a number of delegates from abroad were present.

March 17th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague and the Imperial Commission.

THE Russian authorities continue to watch with the greatest interest the spread of the epidemic of plague in India and to take measures to prevent it crossing their own frontiers. The principal measures undertaken by the Imperial Commission recently formed to deal with the danger are the following:—1. To send a scientific expedition to India to study the disease on the spot. This expedition was to sail from Odessa on the 12th (24th) of February on board one of the large vessels of the Russian volunteer fleet, *en route* for Bombay. At the head of the expedition is Dr. Vuisokovitch, Professor of Pathological Anatomy in the University of St. Vladimir at Kief. He is accompanied by his assistant in the same chair, Dr. Zabolotnui, and one or two senior medical students. The expedition is prepared for a four months' tour, and is instructed to make particular observations on the mode of propagation of the plague in India and the results of inoculations of anti-plague serum both as a preventive and as a curative measure. 2. A second measure is the prohibition for the present year of pilgrimages of Mussulman subjects of the Tsar, whether to Mecca or to the holy places of the Shiite sect, of which Meshed in Persia is the

Hosted by Google

most important. In the same spirit the *Government Messenger*, the official paper of the Government, recently published a proclamation from the Mufti of Orenburg, addressed to all the Imams and others in authority under him. In this proclamation the excellent advice is given to all good Mussulmans to abstain from going to Mecca or Medina this year, and to put off their Haj to a more favourable time, and the wise words of Mahomet are quoted, in which the faithful are told not to go to places where infectious diseases are prevailing, nor, when these diseases come to them, to run into foreign lands and so carry the infection with them. In Russia it is comparatively easy to put a stop to pilgrimages, by merely refusing to issue travelling passports or to give the police-permit to leave the country. The Russian Palestine Society has refused for the present to issue tickets to Christian pilgrims, of whom there is usually a more or less constant stream from Russia to the Holy Land and back. 3. The third measure of the Imperial Commission is to organise means for the preparation of Yersin's plague-serum on a large scale. 4. The fourth is to send small bodies of medical men and officials to the more vulnerable points on the frontiers to take local measures against the admission of the infection to the country. These points are situated along the Persian, Afghan, and Chinese frontiers. Special measures are also being taken along the shores of the Black and Caspian Seas, in the Caucasus, Transcaucasia, Transcaspia, and Central Asia generally. 5. The last measure of the Commission is the decision to publish in the Government gazette all the authentic information they receive about the spread of the plague and the measures that are being taken to guard against it.

The Russian Members of the International Sanitary Conference in Venice.

Russia's official representatives at the Sanitary Conference in Venice are M. Jonin, the Russian Minister in Switzerland, who took part in the similar Conferences in Venice and Dresden which met to deal with the subject of cholera in 1891 and 1892 respectively, and Professor Lukianof, the director of the Imperial (Oldenburg) Institute of Experimental Medicine in St. Petersburg, who has also gone to Venice as the representative of the Imperial Commission appointed to deal with the plague, whose activity has just been described.

Green Tea and the Plague.

Can green tea, imported from India, be a means of introducing the infection of plague? The authorities in the Caucasus appear to think that it may, and have put in action certain rather stringent measures to prevent the possibility of such an event. The importation of green tea is to be stopped at once and all trucks which have carried it are to be disinfected. Chests of tea already unpacked in Batoum are to be isolated and kept so by sentries; tea *en route* is to be stopped at Baku on the Caspian, and there quarantined in the same way. All persons who have been in contact with these goods are to undergo a six days' observation, and on the appearance of any suspicious symptoms are to be at once isolated. Without discussing the desirability of these measures, the question arises why green tea is selected for special treatment apart from other merchandise.

The English Colony in St. Petersburg and the Indian Famine.

A collection was recently made in the English church in St. Petersburg for the sufferers from the famine in India, and reached the large sum of £340. As the English colony numbers only some 3000 individuals (no exact figures are available), and many of these are Nonconformists, this sum must be regarded as a most liberal contribution to the relief of our Indian fellow-subjects.

PHILADELPHIA.

(FROM OUR OWN CORRESPONDENT.)

Cardiac Hydrothorax.

AT a recent meeting of the Pathological Society of this city Dr. J. Dutton Steele presented an interesting statistical paper from the Pepper Laboratory of Clinical Medicine upon the Distribution and Etiology of Cardiac Hydrothorax. An analysis of 2415 necropsies gave 173 cases of uncomplicated chronic heart disease in which there had been long-continued dilatation affecting particularly the right auricle. In the 75 cases of passive effusion into the pleura occurring in this series the effusion was unequal in distribution in 70 per cent., and of this number 77 per cent. were greater upon the right side. In 13 cases the effusion was entirely unilateral, and of these 10 were upon the right side. In equal bilateral hydrothorax the tendency to general anasarca was much increased, and in the unequal cases less than one-sixth showed œdema of any part. The writer reported 5 cases in which there was passive effusion much greater upon or entirely confined to the right side. In all there were undoubted signs of long-continued dilatation of the right auricle, and dropsy of the legs was either absent or followed the appearance of the hydrothorax. In none of the cases were there signs of aneurysm or tumour. The writer thought that the explanation for such effusions is that a dilated auricle by its pressure interferes with the venous and lymphatic circulation of the pleura of the same side, and the long-continued congestion causes the effusion. The right auricle is the most frequently dilated of any of the heart chambers in failing compensation, and hence the large percentage of right-sided effusions.

Infants' Feeding Bottles.

Buffalo, N.Y., has passed an ordinance making it "unlawful for any person or persons to use or to engage in the sale of any bottle, mechanism, or other device for the artificial feeding or nursing of infants or children under three years of age that has connected therewith a rubber tube, hose, or such contrivance." The Health Commissioner, Dr. Ernest Wende, stated that the infant mortality has fallen very materially since its adoption.

The Serum Diagnosis of Typhoid Fever.

In adopting the method of Wyatt Johnston for the diagnosis of typhoid fever, Dr. Gehrmann, of the Chicago Board of Health, has substituted pieces of sterilised mica for card, since the smooth, non-absorbent surface of the former renders it much more easy to effect a solution of the blood in water.

Medical Appointment.

Dr. A. C. Abbott, professor of hygiene in the University of Pennsylvania, has been appointed chief of the Department of Bacteriology of the Philadelphia Bureau of Health, vice Dr. B. Meade Bolton, who has accepted the chair of Pathology in the Missouri Medical College.

Competition among Hospitals.

Philadelphia is soon to have another hospital, to be known as the American Hospital for Diseases of the Stomach. Its scope will, however, be broader than the name implies, for, in addition to the treatment of gastric and intestinal disorders, the management intend to establish a laboratory for research work, giving particular attention to adulteration of food. Free lectures will also be given to the public upon this subject. It is to be hoped that the "charitable feature" of hospital work will be kept prominently in view, and that steps will be taken to prevent abuse as far as this is possible. Competition is so keen among the hospitals that special inducements are offered by some of them to the drivers of our police patrols, "and, of course, the case goes to the highest bidder." I believe the scheme was promulgated by the homœopaths; at all events, the Hahnemann Hospital has been the chief offender. A few of the institutions openly advertise for patients, while others are "written up" by the reporters. It seems that the staff are not averse to appearing in print; indeed, in many cases the technical description is highly suggestive of collusion. Since it is human nature to get as much as one can for nothing, the remedy lies not with the people but with the physicians, and while these latter actually bid for cases abuses of the most flagrant kind will exist.

Feb. 25th.

YORK COUNTY HOSPITAL.—The annual meeting of the York County Hospital was held in the building on March 9th, the Dean of York being in the chair. It was stated that an extension of the children's wards would soon have to be undertaken. The report also mentioned the necessity of taking some steps to improve the accommodation provided for the nurses, and suggested that the work might be carried out during the present year in commemoration of the prolonged reign of the Queen. The accounts showed that at the close of 1896 there was a balance of £141 in the hands of the treasurer.

Obituary.

GEORGE BRETHERTON BARRON, J.P., M.D. ABERD., M.R.C.S. ENG., ETC.

A PRACTITIONER of a most worthy and excellent type has just passed away in the person of Dr. Barron of Southport. He was the son of Mr. William Barron, a medical practitioner of Tarleton, and was educated at King's College, London. He became a Member of the Royal College of Surgeons of England in 1847 and took the degree of M.D. Aberdeen in 1860. He settled down in the former year in Southport, in which town he has practised ever since. Besides his medical work he took a deep interest in all the affairs of the town, was one of the first improvement commissioners, and became a member of the town council in 1867, where his services were so valued that although a strong Conservative he was several times asked by the Liberals to allow himself to be nominated as mayor, but invariably declined the honour. He was a thoroughly earnest and enthusiastic Churchman and a prominent member of the Church Defence Association, while the cause of religious education found in him a most valuable supporter, and he was never tired of aiding national schools with both his time and his money. He was greatly interested in the Volunteer movement and was for a long time surgeon to the 13th Lancashire Rifle Volunteers. Dr. Barron was President of the Lancashire and Cheshire branch of the British Medical Association in 1885 and a representative of that branch on the Council of the Association from 1883 until the time of his death—a period of fourteen years. He was also for many years physician to the Southport Convalescent Hospital and the North Meols Dispensary, and frequently contributed papers on various medical subjects to the columns of THE LANCET. So recently as three or four weeks ago he was in full work, but his illness terminated fatally on March 10th, despite all that could be done for him. Dr. Barron, who was in his seventy-sixth year, leaves a widow and one son, Mr. Herbert G. Barron, who, like his grandfather and his father, is a member of the medical profession. The funeral took place on Saturday, March 13th, and was attended by a large number of every class and creed, all anxious to show respect to the memory of one who was universally loved and honoured as an honest and public-spirited citizen, an able, sympathetic, and kindly adviser in sickness, and a true and very real friend to all who knew him. The Conservative organisations in Southport, Birkdale, Formby, Great Crosby, and Waterloo were represented; also the 3rd V.B. K.L.R., the Church Missionary Society, and the Oddfellows' Society, with all of which bodies the deceased had been closely connected; and the Right Hon. G. N. Curzon, Under-Secretary of State for Foreign Affairs and member of Parliament for the Southport Division of Lancashire, attended specially from London to pay a last tribute of affection to his old friend's memory. Most of the medical practitioners of the town of Southport were also present, whilst the Lancashire and Cheshire Branch of the British Medical Association was represented by Mr. Mitchell Banks of Liverpool, ex-President of the branch; Dr. Samuel Woodcock of Manchester, president-elect; Dr. H. H. Vernon, medical officer of health of Southport and President of the Branch; Dr. R. Harris, a member of council of the Branch; and Dr. Davidson, physician to the Royal Infirmary, Liverpool. By the death of Dr. Barron the world is poorer by the loss of a good man, whilst our profession suffers by the falling out of its ranks of one who well and worthily maintained the dignity and credit of an English general practitioner.

THOMAS DICKINSON, M.R.C.S. ENG., L.S.A. LOND.

MR. THOMAS DICKINSON, late of Sloane-street, whose death occurred on March 3rd, was the son of William Dickinson, an esteemed practitioner of Chelsea. He was educated at King's College School, London, and in due course commenced and finished his medical studies at King's College Hospital under the auspices of Partridge, Daniell, Fergusson, Todd, and Budd. On the conclusion of his hospital career he travelled in Spain for a time in medical charge of a patient. On his return to Chelsea he was appointed medical officer to the district in which he lived, and held that appointment for years, being afterwards elected medical officer to the workhouse. This post he held until the requirements of the Poor-law necessitated the establishment of a new infirmary and the appointment of a resident medical officer. He then settled in Sloane-street, where for many years he conducted a large practice, being medical officer to the Brompton and Belgrave Dispensary and a highly popular practitioner in the neighbourhood. Soon after the establishment of the 1st Middlesex Royal Engineers (Volunteers) he accepted the post of assistant surgeon, as the medical officers were then designated, under the command of Colonel the MacLeod of MacLeod, and in due course was gazetted surgeon. During this time he performed all his military duties to the satisfaction of his commanding officer, taking considerable interest in the corps and being one of the first to pass the Army medical examination which was then required of all medical officers by the Volunteer regulations. Mr. Dickinson was well known among his professional brethren and patients as a cordial, upright, and conscientious man, and those who were acquainted with him socially have to lament in his death the loss of a friend endeared to them by a genial character in all bearings of life. Though busily occupied in professional work, he took an active part in all matters that concerned his fellow parishioners, being interested in and advancing the interests of many local charities and so earning the reputation of an enlightened and conscientious citizen. Mr. Dickinson was a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries of London. He was also for some years on the Council of the Medical College at Epsom, which post he held until a short time before his death. He leaves behind him a widow, a son, Dr. Thomas Vincent Dickinson, and a daughter, the wife of Mr. W. H. Bennett.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. L. von Halban, Professor of Forensic Medicine in the University of Cracow, and for many years editor of the well-known Polish journal, *Przeglad lekarski*. He was fifty-nine years of age.—Dr. T. G. Rowand, formerly Professor of Therapeutics and Materia Medica in the University of Pennsylvania.—Dr. B. Boyer, Professor of Therapeutics in the French School of Medicine, Beyrout.—Dr. Antonio Arantes Pedroso, Professor of Surgical Pathology in the Medical School of Lisbon.—Dr. Caussanel, Professor of the Diseases of Children in the Medical School of Algiers.—Dr. Hartshorne, formerly Professor of Medicine in the University of Pennsylvania.—Dr. Perry Millard, formerly Professor of Surgery in the University of Minnesota.

IN MEMORIAM.—At a meeting of the executive committee of the Merthyr Tydvil Hospital on the 9th inst. a letter was read from Mrs. Harrap and family of Gwaunfarren, Merthyr Tydvil, intimating that it was their wish to subscribe a sufficient sum, presumably from £1300 to £1400, to endow a bed in the accident ward of the hospital as a memorial of the late Mr. Richard Harrap. The offer was gratefully accepted.

THE DIFFUSION OF SMALL-POX.—The outbreak of small-pox which last month threatened the county of London has in a large measure died out. In the four weeks ended on Feb. 27th there were 48 notified cases of the disease in the metropolis, of which total 29 were from the Camberwell sanitary area, and 6 were from the Strand board of works district. In each of these areas, however, the outbreak was limited to a circumscribed locality; but the authorities are to be congratulated on having curtailed the spread of the disease to the small dimensions attained. The registered deaths from small-pox within this period were only 4 in London, but there were 6 additional deaths in the first week of March, whilst last week there was but 1 death, that of a female infant aged under one year, of whose vaccination no statement is forthcoming. There were no cases admitted to the hospital ships last week, and 30 cases remained on board at the close of the week.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having previously passed the necessary examinations and having now attained the legal age of twenty-five years, have been admitted Fellows of the College:—

Linington, William West, L.R.C.P. Lond., St. Mary's Hospital (diploma of Member dates July 27th, 1893).
Sprawson, Frederick Charles, L.R.C.P. Lond., King's College Hospital (diploma of Member dates May 10th, 1894).

The following gentlemen, having passed the necessary examinations, and having conformed to the by-laws and regulations, have been admitted Members of the College:—

Blieden, Max, M.D. Pa., University of Pennsylvania, U.S.A., and St. Bartholomew's Hospital.
Preston, Lionel Litchfield, M.B., B.S. Durh., L.S.A. Lond., University of Durham and Middlesex Hospital.

INTER-HOSPITAL FOOTBALL.—The final tie of the competition for the Hospitals Association Cup took place on Wednesday last at the Essex County Ground, Leyton, and was won after a good game by Guy's Hospital, who beat London Hospital by one goal to none.

UNIVERSITY OF CAMBRIDGE.—Professor Rucker, F.R.S., has been appointed Reade lecturer for the present year. Mr. F. F. Blackman, of St. John's College, has been appointed University Lecturer in Botany. Dr. Arthur Willey, whose recent discovery of the eggs of nautilus has excited much interest, has been elected to the Balfour Studentship in Animal Morphology for another year. The debate on the proposal to confer titular degrees on women has run to the unprecedented length of three days. Special numbers of the *Reporter* containing the report of the Syndicate and the speeches delivered will be published, and may be had (price 7*d*.) on application to the University Press. At the congregation on March 11th the following medical degrees were conferred:—M.D.: C. W. Windsor, M.A., non-collegiate. M.B.: W. G. Richards, B.A., Christ's. M.B. and B.C.: A. S. J. Pearse, M.A., Trinity; H. C. Haslam, B.A., Caius; F. G. Thomas, B.A., Caius; J. T. Wills, B.A., Caius; R. de S. Stawell, B.A., Trinity Hall; C. B. Stewart, M.A., Christ's. A welcome of extraordinary enthusiasm was given to Dr. Nansen by a crowded congregation on March 16th, when the honorary degree of Doctor in Science was conferred upon him.

DIPHTHERIA IN LONDON.—In the four weeks ended Feb. 27th the notified cases of diphtheria in London were 916 in number, every one of the sanitary areas of the county being invaded, though five of them had only 9 notified cases in all among them. But the other four districts had an aggregate number of 299 notifications, or nearly one-third of the total for the whole of London; and if the other four districts, each with 39 and more notifications, be taken, then we find that in eight of the sanitary areas there occurred more than one-half of the total notifications in the county, comprised of forty-three sanitary districts—excluding, that is, the Port of London. The weekly average of notified cases in the period under review was 229. The registered deaths, 185 in all, yielded a weekly average of 46. The case mortality per cent. of notifications was thus 20·2. Comparing the period with that preceding it, namely, the four weeks ended Jan. 30th, we find that the weekly average of notified cases in the earlier period was 239, though the per case mortality was as high as 26·1 per cent. Thus we find in the February period a distinctly favourable state of affairs, particularly when it is remembered that the January period compared favourably with its predecessors. In the two weeks of March ended the 13th the registered deaths in London were 43 and 53. The latter total was 21 in excess of the corrected decennial average for the tenth week of the period 1887–96. Two of the deaths were of infants under one year of age, and two of persons aged over twenty years. Wandsworth is credited with 8 of the deaths, Camberwell with 5, and Kensington, St. Pancras, Hackney, and Bethnal-green each with 4 deaths. The admissions to hospital in the week numbered 97, against 104, 102, and 112 in the preceding three weeks, and on Saturday last there were 834 cases still under treatment. In the "Outer Ring" 10 deaths from diphtheria were registered, of which 4 were in the Edmonton district.

THE JENNY LIND INFIRMARY, NORWICH.—In commemoration of the sixtieth year of the Queen's reign it has been decided to collect a sum of money to be called the Diamond Jubilee Fund, for the purpose of building at Norwich a new Jenny Lind Infirmary for Sick Children. A site for the building has been presented by Mr. J. J. Colman, and the Earl of Leicester (Lord-Lieutenant of the county) has given a donation of £2000. The present Jenny Lind Infirmary was established in 1853 and has twenty-six beds.

CIRENCESTER COTTAGE HOSPITAL.—The annual meeting of Cirencester Cottage Hospital was held on March 2nd, under the presidency of the Ven. Archdeacon Hayward. The twenty-second report of the committee showed that 101 new cases were admitted during the year, making 1993 during the twenty-two years the hospital had been opened. Structural additions and improvements had been made to the building at a cost of £420, which had been paid out of the reserve fund. The ordinary receipts had been £588 and the expenses £430.

PLURALISTS.—At the last meeting of the Kidwelly Town Council it was stated that only one application had been received for the amalgamated appointment of road surveyor, sanitary inspector, lamp-lighter, water inspector, building inspector, and quay caretaker and collector, for which a salary of a guinea a week had been offered. It was finally resolved to re-appoint the former road surveyor and to add to his office that of building inspector, and also to invite applications for the amalgamated offices of sanitary inspector, water inspector, lamp-lighter, and quay inspector at a salary of fifteen shillings a week.

GLOUCESTER DISTRICT NURSING SOCIETY.—The annual meeting of this society was held on March 4th, under the presidency of Dean Spence. The report showed that the receipts were £490, against £565 in the preceding year, and the expenditure was £630, against £550. It was decided to affiliate with the Victoria Jubilee Institute for Nurses. The £1461 balance from the small-pox nursing fund publicly subscribed had been invested in Consols, and it was thought that the donors would consider the erection of a permanent nurses' institute as a fitting application of the money.

SWANSEA NURSING INSTITUTE.—The annual meeting of the Swansea Nursing Institute was held on Feb. 22nd, under the presidency of the Mayor. The annual report stated that there were seventeen nurses on the staff. A district nurse who had been appointed was doing excellent work amongst the poor, and an anonymous donor had promised to defray the expense of another. The earnings of the nurses had exceeded those of the previous year by £61, the total being £822. Mrs. Llewelyn had given £500 towards the cost of the house, which had been £1172 This Nursing Institute is carrying on a most useful work at Swansea.

PROPOSED COTTAGE HOSPITAL FOR PENARTH.—At a meeting held at Penarth on March 3rd it was unanimously resolved to celebrate the Queen's Diamond Jubilee by the erection of a cottage hospital. The chairman said that to carry this out efficiently at least £2500 would be required. The structure would be intended to accommodate ten or twelve beds, at an estimated cost of £50 per bed. Mr. R. F. Nell, M.R.C.S.Eng., L.S.A., stated that the medical men of Penarth were desirous that such an institution should be established to save the necessity and expense of sending patients to Cardiff and to relieve their sufferings immediately on the spot.

THE DELAY IN ASSIZE TRIALS.—In the recently published Blue book on Judicial and Criminal Statistics for 1895, pages 33 to 35 and 175 to 178 deal specially with the detention of prisoners awaiting the assizes. This subject has not hitherto been given a place in the Blue-book; the fact that this information was to be published was made known in the House of Commons on Feb. 18th by the Home Secretary in the course of a reply to Mr. Henniker Heaton, who had called the attention of the Government to several instances in which hardships had been inflicted under the present system. Mr. Heaton gave details of eleven cases occurring during the last three years in which persons had been acquitted at Maidstone Assizes, six of them having been in prison awaiting trial for over three months, two for over four months, two for over five months, and one for over six months.

Hosted by Google

H.R.H. PRINCESS CHRISTIAN has fixed May 6th for the St. John Ambulance *fête* and competition at the Crystal Palace in commemoration of the Queen's Diamond Jubilee.

METROPOLITAN CONVALESCENT INSTITUTION.—The annual meeting of the Metropolitan Convalescent Institution was held on Feb. 23rd at the office, 32, Sackville-street, Mr. Richard B. Wade presiding. It was stated in the report that during the past year 5064 men, women, and children were admitted to the homes.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST.—The annual meeting of the Royal Hospital for Diseases of the Chest, City-road, was held on March 15th, the Lord Mayor presiding. The report showed that 742 in-patients were under treatment during the year, and there were 9600 out-patients, who made upwards of 24,000 attendances. The total income, including £2800 received from legacies, was £10,108, and the total expenditure was £7459.

HASTINGS AND EAST SUSSEX HOSPITAL.—The annual meeting of the Hastings and East Sussex Hospital was held in the building on March 9th, the Mayor of Hastings being in the chair. At the beginning of the year forty-eight in-patients remained under treatment, and 634 were admitted in the course of the year; the average stay in the hospital was between nineteen and twenty days. The financial position of the charity was much better last year than during the previous year, the credit for this result being mainly due to a committee of ladies, who raised £1001.

MUNICIPAL HONOURS TO MEDICAL MEN.—A correspondent reminds us in a letter from Australia that Mr. Hall Owen, M.R.C.S.Eng., M.R.C.P.Irel., is the present Mayor of the city of South Melbourne, a city with 36,000 inhabitants and prior to the period of depression of 46,000 inhabitants; and that Dr. Cascaden is the present Mayor of the adjoining town of Port Melbourne, both gentlemen having been unanimously elected. Our correspondent considers, and so do we, that members of the profession at home like to learn of instances of honour done and trust confided to members of the profession abroad.

THE DENTAL HOSPITAL OF LONDON.—Lord Kinnaird presided over the thirty-ninth annual meeting of this institution, which was held on the 11th inst. at the hospital in Leicester-square. The report was one of a congratulatory kind, testifying again to the continued and increasing usefulness of this important charity. During the year 1896 no less than 57,654 cases had been attended to, many of them being treated for preservation of existing teeth rather than extraction. It was hoped soon to proceed with the building of the new hospital and school, the present premises being totally inadequate for the purpose and considerably hampering the extension of the good work now going on, both educational and charitable. The committee appeal for donations and subscriptions, which may be sent to the secretary, Mr. J. F. Pink, at the hospital, Leicester-square, W.C.

PRESENTATIONS TO MEDICAL MEN.—Dr. G. Burbidge White of South Richmond-street, Dublin, was presented at a recent meeting of the Committee of Inspection of the Masonic Grand Lodge of Ireland with a purse containing the fees for the M.D. degree of Dublin University. The presentation was made as a testimony of esteem and recognition of medical services rendered in the interests of the committee.—Mr. Norman G. Douglas, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Scarborough, was the recipient, on the 1st inst., at a meeting of the Central Evening Continuation Board Schools, on the close of the classes which he has held on "Ambulance Aid" and "Sick Nursing," with a silver cigar-case in appreciation of his services.—At a successful entertainment and concert, in the Lostock Hall Mission School, Preston, on the 1st inst., the proceeds of which were in aid of the local ambulance corps, Mr. Thomas Sharples, L.R.C.P., L.R.C.S. Edin., the instructor, was presented by the members of the classes with two volumes of Dr. Nansen's new work.—On the 2nd inst., in the Roman Catholic School, Brownedge, Bamber Bridge, on the distribution of certificates and medallions in connexion with the local branch of the St. John Ambulance Corps, Miss Whitehead, on behalf of the ladies' sick nursing and first-aid class, presented to Mr. C. J. Trimble, L.R.C.P. Edin., D.P.H., a silver cigarette case, as a token of gratitude for his ambulance instruction.—At the annual general meeting of the Governors of the Wolverhampton and Staffordshire General Hospital, held on the 9th inst. a portrait of himself, painted in oils, was presented to Dr. Totherick by Canon Davies, a member of the committee, and in the name of the subscribers, together with a facsimile in an oak cabinet, bearing the following inscription: "To James Yeomans Totherick, M.D., M.R.C.P.E. We, the undersigned, on behalf of a large number of friends and admirers, beg your acceptance of your portrait in oils, together with this memento of the occasion, as an expression of the high esteem in which you are held by all classes of society, and in recognition of your valuable and faithful services for the past twenty-five years as hon. physician to the Wolverhampton and Staffordshire General Hospital." As a memorial of Dr. Totherick's long connexion with the hospital it is intended to hang the portrait in the institution.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Metropolitan Poor-law Children.

SEVERAL Members of the House of Commons have been interesting themselves in the draft order of the Local Government Board on this subject, and if opportunity offers they will raise a general debate in the hope that the Local Government Board may be induced to re-consider their decision.

Midwifery Orders in Poor-law Unions.

It is the purpose of Mr. Heywood Johnstone to move next week for a return showing with regard to each Union in England and Wales the number of confinements in the workhouses during 1896 and the number of orders in respect thereof given to visiting medical officers under the general order of the Poor-law Commissioners, the total amount paid to the medical officers in respect of the orders, the number of orders given to district medical officers in respect of confinements other than in the workhouse and the amount paid in respect of them, and the number of district nurses appointed under the general order of the Local Government Board.

HOUSE OF COMMONS.

THURSDAY, MARCH 11TH.

Suppression of Rabies.

Mr. Walter Long, replying to Mr. Stephens, said he was aware that a dog was killed by the police at Hendon on March 4th, and that upon post-mortem examination by the county veterinary inspector rabies was found to be present. Every possible effort was being made to expedite the completion of the arrangements the Board of Agriculture proposed to make for the suppression of rabies.

The London Water Question.

At this sitting of the House there was a long debate on the London water question in connexion with a series of eight Bills for the purchase of the undertakings of a similar number of the water companies. Mr. Sydney Buxton introduced the subject by moving the second reading of the first of the Bills—that for the purchase of the undertaking of the Chelsea Company. He claimed for the London County Council that the time had come when the water companies should no longer be private concerns, but be in the possession and under the control of the ratepayers.—Sir F. Dixon-Hartland moved the rejection of the Bill, claiming that its terms were unfair both to the ratepayers of London and to the shareholders of the company. Mr. Chaplin intimated that the Government would oppose this and the other Bills, but would be willing to appoint another Royal Commission, and in the meantime introduce a measure to strengthen and improve the position of the water consumers in the metropolis by giving them easier redress when they were aggrieved by failure to fulfil obligations on the part of the water companies. The debate went on for five hours, the result being that the Chelsea Bill was rejected by 258 to 123 votes, and in consequence of this decision the other seven Bills were withdrawn.

FRIDAY, MARCH 12TH.

Experiments on Living Animals.

Mr. MacNeill asked the Secretary of State for the Home Department, in view of the fact that in the return showing the number of experiments performed in the year 1895 on the bodies of living animals in the United Kingdom, amounting in all to 4679, of which 3119 were performed under special certificates dispensing with anæsthetics, the term "experiment" meant the whole series of experiments carried out on a particular line of research, and that 200 or 300 animals were at times used in a single experiment, while 80 or 90 was a common number; whether there was any record kept of the number of animals used in the 4679 experiments of 1895; and whether he would, under the powers conferred upon him by 39 and 40 Vic., c. 77, s. 9, direct that the vivisectors in making reports for the vivisectors' return for 1896 should state the number of animals used in each experiment.—Sir Matthew White Ridley replied: The hon. Member is under an entire misapprehension. The number of animals used does not exceed the number of experiments given in the return. In fact, it is less.—Mr. MacNeill further asked the Home Secretary whether the inspectors appointed under 39 and 40 Vic., c. 77, for the purpose of securing a compliance with the provisions of that Act to visit places registered for

Hosted by Google

vivisection, did in fact visit such places during the performance of experiments on the bodies of living animals; whether they inspected the bodies of the vivisected animals after the performance of these experiments, or were usually present at vivisections, and did they usually see the bodies of the vivisected animals; had the inspectors any power to mitigate or prevent the infliction of pain on animals by vivisectors who experimented under Special Certificate A, which permitted its holder to experiment without anæsthetics; and would he state in what degree or to what extent inspection operated as a prevention of unnecessary pain being inflicted on living animals.—Sir Matthew White Ridley replied; Yes sir, the inspectors both visit registered premises during the performance of these experiments and see the bodies of animals upon which experiments have been performed. Certificate A is never allowed except for inoculations and similar trivial operations, and in every case a condition is attached to prevent unnecessary pain. The safeguards against the infliction of unnecessary pain are the character of the persons to whom licences are given, the careful inquiry that is made by the Home Office beforehand, and, lastly, the stringent conditions under which licences are given and certificates allowed, and which it is the duty of the inspectors to see are properly observed.

Darenth Asylum.

Mr. Chaplin, replying to Mr. Pickersgill, said he was informed that there were no children at the Darenth Asylum who were feeble minded but not imbecile. The children at the asylum were legally paupers. It was not the intention to remove the children from the asylum.

The Health of the 2nd Essex Regiment.

Mr. Sinclair asked the Under Secretary of State for War whether fever had broken out in the 2nd Battalion of the Essex Regiment now stationed in India, and if so could he state to what extent; and whether, seeing that the 2nd Battalion of the Essex Regiment left England in 1882 for foreign service and had never returned to the United Kingdom since that time, the Secretary of State for War would recall that battalion home as soon as possible to allow it to be stationed in its own county for a time after such a lengthened period of foreign service.—Mr. Brodrick replied that in the return from the battalion dated Feb. 1st the health was described as "indifferent," but the numbers in hospital were about normal and the prevailing diseases appeared to be of a specific character. The average tour abroad of an infantry regiment was seventeen years. The 2nd Battalion of the Essex Regiment left England in 1882 and was ninth on the roster for return home.

New Regulations for Wool-sorting.

Sir Matthew White Ridley, in reply to Sir Charles Dilke, said that the special rules with regard to the wool-sorting industry were being served upon the occupiers of factories and workshops to which they applied.

The Unhealthiness of Sierra Leone.

Mr. Price asked the Secretary of State for the Colonies whether he had any confirmation of the report that during the first seven months of 1896 out of about twenty English officials in the colony of Sierra Leone there were three deaths and five cases in which the officials had to be invalided home; whether officials had to serve fifteen months at Sierra Leone before obtaining leave, whereas in the Gold Coast colony they had only to serve twelve months; and whether, seeing that Europeans were particularly subject to illness during the later months of their stay on the coast, the Colonial Office could see its way to making the rules as to leave in Sierra Leone the same as in the Gold Coast colony.—Mr. Chamberlain said, in reply: I regret to state that during the months in question, which were exceptionally unhealthy, no less than five deaths occurred among the English civil officials, of whom there were about thirty, and three were invalided home, besides two (including the Governor) who were invalided to the Canary Islands. The periods for which officials have to serve in Sierra Leone and the Gold Coast before obtaining ordinary leave are as stated, but in case of illness sick leave is granted sooner. It does not appear that Europeans are more subject to illness during the later months of their stay than during the earlier ones; and, while I am anxious that everything possible should be done to improve the conditions of life on the Coast, I do not think that a sufficient case has yet been made out for reducing the tour of service in Sierra Leone to twelve months and throwing a considerable burden on the finances of the colony. Sierra Leone, as far as statistics go, is more healthy than the Gold Coast.

MONDAY, MARCH 15TH.

Exercise for Prisoners.

Mr. Pickersgill asked the Secretary of State for the Home Department whether he was aware that a convict undergoing the preliminary stage of his term had for a period of nine months to work, eat, and sleep in one small cell, in which he was confined for twenty-three hours out of every twenty-four at all seasons of the year; whether he was aware that several principal officers of prisons had described this confinement as excessive and as producing injurious results, both moral and physical; and whether he would confer with the Prison Commissioners with a view to the granting to this class of prisoners more than one hour's exercise per diem. — Sir Matthew White Ridley said he was aware that a convict under a sentence of penal servitude, with the exception of his daily attendance at chapel and hour of exercise, passed the first nine months of his sentence in separate confinement. He believed the hon. member to be misinformed as to the opinions held by the principal officers of the prisons in which convicts were received with regard to the effects of this confinement. The amount of exercise necessary for the health of each prisoner was left by statute to be determined by the prison surgeon, and he was perfectly content that under that statute the surgeons should exercise a liberal discretion.—Mr. Pickersgill further asked the right hon. gentleman whether he was aware that the Governor of Dartmoor Prison had condemned the system of separate confinement for nine months before the departmental committee which inquired into the subject.—Sir Matthew White Ridley said he was not aware of it.

Reformatories for Inebriates.

Sir Matthew White Ridley, replying to a question addressed to him by Mr. Hobhouse, said he was afraid he could not say when the Bill for the establishment of reformatories for inebriates was likely to be introduced. The Bill had been for some time in a forward state of preparation, but there were still remaining some important points which required to be settled.

The Lunacy Question.

Sir Matthew White Ridley informed Mr. Hobhouse that the inquiry into the causes of the increase of lunacy in England and Wales had been made and the report laid on the table of the House. Copies of the report would be delivered to Members almost immediately.

Death in a Lunatic Asylum.

Mr. Murnaghan asked the Chief Secretary to the Lord Lieutenant of Ireland—(1) whether his attention had been called to the verdict of the coroner's jury recently given at Belfast at the inquest on the body of Mrs. Beggs, who died in the Belfast Lunatic Asylum; (2) whether he was aware that the eminent medical man who conducted the post-mortem examination found a number of her ribs and breast bone broken, and that the jury found that the bones were not broken at the time she was taken from her home to the asylum; (3) whether the medical officers of the asylum had at any time, and if so at what date, discovered that her bones were broken; and (4) whether, considering the facts disclosed at the inquest, the Government would, in the interests of inmates of lunatic asylums, have further inquiry made into the matter.—Mr. Gerald Balfour replied that the facts were as stated in the first and second paragraphs of the question. The verdict of the coroner's jury was that the injuries were not received at the patient's home, and that there was no evidence to show when and how they had been received. Deceased was admitted to the asylum on Jan. 5th, and on Jan. 21st the asylum medical officers discovered the injuries. An inquiry had been held into the matter by the inspectors of lunatic asylums, who would forward their report to the board of governors of the asylum.

TUESDAY, MARCH 16TH.

Metropolitan Pauper Children.

Mr. T. W. Russell, replying to a question on this subject, said that the President of the Local Government Board understood from the report of the proceedings at the Conference of Poor-law Guardians held to consider the draft order that the voting on the resolution to the effect that it was desirable that separate provision such as was indicated in the draft order should be made for special classes of children was 63 for and 15 against; and that the resolution to the effect that the Local Government Board, before constituting a new board, should consider whether the duties created by the order could not be carried out by some existing authority or authorities was carried by a majority of 42 votes—56 voting for and 14 against the resolution. The President had been informed of the resolution which had been passed by the London County Council to the effect that, while recognising the necessity for alteration in the present mode of dealing with the class of children referred to, the Council were of opinion that the establishment of a new and distinct metropolitan central authority for the care of a section of Poor-law children was undesirable and calculated to lead to needless expense. He had also received a copy of a report of the general purposes committee of the Metropolitan Asylums Board (which report was adopted by the managers on Saturday last) expressing their willingness to undertake the care of all or any of the classes of children referred to. The representations which had been made to the President in favour of the managers of the Asylums District undertaking the duty, in preference to the constitution of a new board of managers, would receive his careful consideration. He could not, however, give any undertaking to postpone the official promulgation of a permanent order until an opportunity had been given to the House to discuss the subject.

Medical Officers to Volunteer Corps.

Mr. Brodrick said, in reply to Colonel Dalbiac, that the question had been carefully considered by the War Office, and it had not been thought necessary to extend the joining allowance now given to combatant Volunteer officers to the medical officers.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ARBUCKLE, H. W., M.D. Aberd., L.R.C.P. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer for Stainforth.

ARKLE, C. J., M.D. Lond., M.R.C.P., has been appointed Assistant Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.

BARLING, A. S., L.R.C.P. Lond., M.R.C.S., has been appointed an additional Honorary Surgeon to the Royal Lancaster Infirmary.

BLAKISTON, A. A., M.R.C.S., has been re-appointed Medical Officer by the Glastonbury Town Council.

BISDEE, A. J., M.R.C.S., has been re-appointed Medical Officer for the Stansted Sanitary District.

BOWER, W. G., L.R.C.P. Lond., M.R.C.S., has been appointed an Honorary Physician to the Sheffield Hospital for Ear, Throat, and Skin Diseases.

BRYANT, C. H., M.B., B.S. Durh., F.R.C.S. Eng., L.R.C.P., M.R.C.S., has been appointed House Surgeon to the Sussex County Hospital, Brighton, vice A. H. Buck, resigned.

BURGESS, ARTHUR H., M.B. Vict., L.R.C.P. Lond., M.R.C.S., has been appointed a Junior Resident Medical Officer for the Manchester Children's Hospital.

CULLEN, JOSEPH J., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Castlenock Dispensary District, vice R. F. Maguire.

FELLOWS, F. M., M.B., C M. Edin., has been appointed House Surgeon to the General Hospital, Great Yarmouth, vice R. W. Montserrat, resigned.

GANNER, JOSEPH, M.B. Lond., L.R.C.P., M.R.C.S., has been appointed a House Physician to the Birmingham General Hospital.

GAYLOR, EDWARD, L.R.C.P. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer by the Alfreton Urban District Council.

Hosted by Google

GIBSON, E. ARTHUR, M.B., C.M. Glasg., L.M. Rotunda, has been appointed Obstetric Physician to the Glasgow Training Homes for Nurses, vice A. W. Russell.

HAMILTON, JOHN, M.D. Durh., F.R.C.S., L.R.C.P. Edin., has been re-appointed Medical Officer of Health by the Swadlincote District Council.

HELME, W, C., M.B., C.M. Edin., has been appointed an additional Honorary Surgeon to the Royal Lancaster Infirmary.

HINDE, F. R. B., M.D. Edin., M.R.C.S., has been re-appointed Medical Officer for the Sawbridgeworth Sanitary District of the Bishop Stortford Union.

HUNT, A. H. W., L.R.C.P. Lond., M.R.C.S., has been re-appointed an Honorary Gynæcologist to the Wolverhampton and Staffordshire Hospital.

JONES, S. LLOYD, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Junior Medical Officer to the London County Asylum, Colney Hatch, Middlesex.

JONES, T. C., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed an Honorary Physician to the Sheffield Hospital for Ear, Throat, and Skin Diseases.

JOSCELYNE, ARTHUR E., M.R.C.S., L.R.C.P., L.S.A., has been appointed Medical Officer with charge of Out-patients to the Miller Hospital, Greenwich, vice W. T. B. Donelly, deceased.

LAMPORT, H. C., M.B, C.M. Edin., has been appointed an additional Honorary Surgeon to the Royal Lancaster Infirmary.

LITTLEJOHN, HARVEY, M.A., M.B., B.Sc., F.R.C.S. Edin., has been appointed Lecturer on Medical Jurisprudence and Public Health at the School of Medicine, Surgeon's Hall, Edinburgh, vice Sir H. D. Littlejohn.

LOGAN, R. R. W., M.R.C.S., has been re-appointed Medical Officer of Health by the Hartshorne and Measham Rural District Council.

MARSH, F., F.R.C.S., L.R.C.P. Lond., has been appointed a Surgeon for the Birmingham and Midland Ear and Throat Hospital.

MORTON, W. BRITAIN, M D. Lond., L.R.C.P., M.R.C.S. Eng., has been appointed Resident Medical Officer at Brislington House, Bristol.

PHILPS, F. G. M., M.R.C.S., L R.C.P. Lond., has been appointed Clinical Assistant to Out-patients at the Chelsea Hospital for Women.

ROSS, D. M., M.D. Durh., F.R.C.S., M.R.C.P. Lond., has been appointed an Honorary Medical Officer for the Cottage Hospital, Boscombe, vice P. W. G. Nunn, resigned.

ROUSE, E., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer of Health by the Barnstaple Port Sanitary Authority.

SCOTT, H. AINSLIE, M.B., Ch.B. Vict., M.R.C.S., L.R.C.P. Lond., has been appointed a Junior House Surgeon to the Ancoats Hospital, Manchester.

SIMON, R. M., M.D. Camb., L R C.P. Lond., M.R.C.S., has been appointed to the Professorship of Forensic Medicine, Mason College, Birmingham, vice J. St. S. Wilders, resigned.

SOMERVILLE, GEO. L., M.B., C.M. Edin., has been appointed an Honorary Medical Officer for the Stockton Hospital.

STANLEY, DOUGLAS, M.D. Edin., M.R.C.P. Lond., has been appointed Extra Acting Physician to the Children's Hospital, Birmingham, vice G. W. Powell.

TORNEY, G. PARSONS, B.A., L.R.C.S. Irel., L.R.C.P. Irel., L.M., has been appointed Medical Superintendent of the Lincolnshire County Asylum.

TUCKETT, W. R., M.R.C.S., has been re-appointed Medical Officer to the Charnwood Forest Convalescent Home.

WILLIAMS, E. R., M.R.C.S., L.R.C.P. Lond., has been appointed Surgeon-Lieutenant to the 1st V.B. the Welsh Regiment.

WRIGHT, W. H., L.R.C.P. Irel., M.R.C.S., has been re-appointed Medical Officer of Health by the Alvaston and Boulton District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BETHLEM HOSPITAL.—Two Resident Clinical Assistants for six months Apartments, complete board, and washing provided.

BIRKENHEAD UNION.—Assistant Medical Officer for one year, for the Infirmary, Workhouse and Schools. Salary £80 per annum, with board, washing, and apartments. Applications to the Clerk to the Guardians, Clerk's Offices, 45, Hamilton-square, Birkenhead.

BOOTLE BOROUGH HOSPITAL.—Junior House Surgeon. Salary £40 per annum, with board, lodging, washing, &c.

COUNTY BOROUGH OF SOUTHAMPTON.—Assistant to the Medical Officer of Health. Salary £150 per annum. Applications to the Town Clerk, Municipal Offices, Southampton.

DENTAL HOSPITAL OF LONDON, Leicester-square.—Assistant Dental Surgeon.

DEVON AND EXETER HOSPITAL, Exeter.—Assistant House Surgeon. Salary £140 per annum, with board and lodging, not including alcoholic liquors and aerated waters.

DISTRICT INFIRMARY, Ashton-under-Lyne.—House Surgeon. Salary £100 a year with board and lodging.

GENERAL HOSPITAL, Birmingham.—Surgical Casualty Officer for one year. Salary £50 per annum, non-resident.

GENERAL HOSPITAL, Nottingham.—Assistant House Surgeon for six months. Board, lodging, and washing in the hospital provided.

GUEST HOSPITAL, Dudley.—Resident Assistant House Surgeon for six months. Board, lodging, and washing in hospital provided.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians.

HOSPITAL FOR DISEASES OF THE THROAT, Golden square, London, W.—Junior Resident Medical Officer for six months. Salary at the rate of £25 per annum, with board, lodging, and washing.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST AND THROAT, 26, Margaret-street, Cavendish-square, London, W.—Physician in Ordinary. Also Visiting Physician.

LONDON SCHOOL OF MEDICINE FOR WOMEN, 30, Handel-street, Brunswick-square, W.C.—Demonstrator of Physiology. Salary £30 per annum

MANCHESTER ROYAL EYE HOSPITAL.—House Surgeon. Salary £70 per annum, with residence, board, and washing.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury, London.—Senior House Physician. Salary £100, with board and apartments.

NEWPORT AND MONMOUTHSHIRE HOSPITAL, Newport, Mon.—House Surgeon. Salary £100 per annum, with board and residence (no stimulants provided).

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, London.—Assistant Resident Medical Officer for four months. Salary at the rate of £50 per annum, with board and residence.

ROXBURGH DISTRICT ASYLUM, Melrose.—Assistant Medical Officer. Salary £100 a year, with board, rooms, attendance, and washing.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road, Brighton.—House Surgeon. Salary £80 per annum, with board, lodging, and washing. No stimulants.

ROYAL FREE HOSPITAL, Gray's-inn-road, London.—Assistant Physician for Out-patients.

ROYAL SURREY COUNTY HOSPITAL, Guildford.—Assistant House Surgeon. Board, residence, and laundry provided.

ST. LUKE'S HOSPITAL, LONDON, S.E.—Clinical Assistant for six months. Board and residence provided.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, London, E.C.—House Surgeon. Salary £50 per annum, with board and lodging.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington.—Curator of Museum and Demonstrator of Pathology.

ST. SAVIOUR'S UNION, Surrey.—Medical Superintendent and Second Assistant Medical Officer at the Infirmary, East Dulwich-grove, S.E. The salary of the Medical Superintendent at the rate of £400 per annum, with unfurnished house, coals, gas, and water, and that of the Second Assistant Medical Officer at the rate of £80 per annum, with furnished apartments, board, and washing. Subject to an annual percentage deduction from the salaries in accordance with the provisions of the Poor-law Officers Superannuation Act. Applications to the Clerk, Union Offices, John-street, Blackfriars-road, S.E.

UNIVERSITY COLLEGE, BRISTOL, FACULTY OF MEDICINE.—Medical Tutor, Stipend £125 per annum.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF, MEDICAL SCHOOL.—Demonstrator in Physiology for the Summer Session.

VICTORIA HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Edinburgh.—Resident Physician. Board and lodging are provided, and an allowance for conveyance at the rate of £24 per annum. Also non-resident Medical Officer for Out-patients. Salary at the rate of £60 per annum. The appointments for six months Applications to Messrs. Wallace and Guthrie, W.S., 1, North Charlotte-street, Edinburgh, Hon. Secs.

WESTERN GENERAL DISPENSARY, Marylebone-road, London —House Surgeon, unmarried. Salary £60 a year, with board and residence.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £60 per annum, with board and residence in the hospital.

ROYAL INSTITUTION.—9 P.M. Sir W. Turner: Early Man in Scotland.

SATURDAY (27th).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Inspection and Demonstration at Harrison and Barber's Knacker Yard, Whitechapel.

ROYAL INSTITUTION.—3 P.M. Right Hon. Lord Rayleigh: Electricity and Electrical Vibrations.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second volume of 1896 was given in the issue of Dec. 26th last. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

CIRRHOSIS OF THE LIVER IN CHILDREN.

To the Editors of THE LANCET.

SIRS,—I should be glad if any of your readers could refer me to literature on the subject of cirrhosis of the liver in children. I have recently met with a typical case of "hob-nailed" liver in a negro child of seven years, and I am constantly seeing cases of ascites in young native children, most of which I am certain are associated with hepatic contraction.

I am, Sirs, yours truly,

W. M. ELLIOTT, M.D. R.U.I.

Salt Pond, Gold Coast, Feb. 9th, 1897.

Hosted by Google

SUPERFŒTATION.

To the Editors of THE LANCET.

SIRS,—I am allowed by the kindness of Dr. J. Hutchinson Swanton to publish this case. I attended a woman in her confinement on Jan. 6th. Her abdominal tumour was abnormally large, the membranes were intact, and I could feel two well-developed feet through them. Pains being strong and the os uteri well open, I ruptured and much liquor amnii escaped. On a second examination I found another bag of membrane presenting. I ruptured this also and felt a soft mass which was speedily expelled, and proved to be the head of a fœtus apparently about three intra-uterine months of age. From its navel projected an exomphalos about as large as an orange containing intestine. The second child was then rapidly delivered, and proved a large, healthy, and lusty male of full term. There were then expelled two distinct and separate amnia and placentæ to which distinct funes were attached. The small fœtus had been dead apparently about three weeks, and I am surprised that labour did not set in earlier, but the mother stated that she had been in pain about three weeks. It appears to me probable that a second ovum was fertilised in utero after the first had been attached five months. The mother is very strong and the uterus and os uteri were exceptionally large. I cannot conceive the fœtus in question to have been dead six months in utero, as the skin was not macerated and the general appearance seemed to indicate that it had not long been dead. I am, Sirs, yours faithfully,

Edmonton, Middlesex, Feb. 10th, 1897. EDWARD C. B. IBOTSON.

*** The overwhelming probability is that the two ova were fertilised at the same time, and that the one died at the end of three months and was retained till term.—Ed. L.

Ethics.—Our attention has been called to the communication in question. We agree with our correspondent.

ALLEGED REDUCTION OF CONSULTANTS' FEES IN LONDON.

THE *Medical Record* of New York of Feb. 20th contains a paragraph to the effect that it is regarded as undignified for a consultant in the West-end of London to accept any less fee than two guineas, and that the result is that all the fees go to those of established reputation. Our contemporary adds that it is now proposed to recognise as strictly professional the acceptance of reduced fees even as low as 7*s.* We hope this statement will not be taken too seriously. Certainly we are not aware of any valid foundation for it. No doubt the *amour propre* of high consultants leads them occasionally to take patients who could pay a sufficient but modest fee into their hospital as charitable patients rather than hand them over to a younger colleague who would only be too thankful for such a fee. This is a sore evil which needs only to be exposed to be remedied. It is a part of the great question of abuse of hospitals. But the reduction of consultants' fees to 7*s.* is not to be thought of. It is of a piece with sixpenny dispensaries, and should be resisted by every practitioner who respects himself and his profession. The two guineas fee of the established consultant is right enough. It is even to be wished that the more leading consultants would place a higher value on their services and so lead to a better distribution of work. But to reduce the consultants' fee to less than the traditional guinea when the nation is many times wealthier than when such a fee was established is to be unfaithful to the profession and its enormous responsibilities.

M.O.H.—The best plan is simply to wash the floor and woodwork with a 1 in 1000 solution and then with soap and water. Where washable papers are in use such a proceeding would not injure them in the least. A steam spray, as, for instance, that of Siegels, is also useful for applying corrosive sublimate solution, in which case it should be of 1 in 500 strength. There should be no risk attending the use of weak solutions such as these, but of course the stock should be kept out of the way. The L.G.B. soloids of corrosive sublimate (Messrs. Burroughs, Wellcome, and Co.) are very convenient.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—I shall feel much obliged if any of your readers can inform me of an institute where a patient of mine can be placed as a permanent resident. He is about thirty years of age, and though not quite imbecile requires careful watching; he is dirty in his habits. His means are small and his friends do not wish to be subjected to a greater expense than about £50 annually. I am, Sirs, yours truly,

March 15th, 1897. C. E. F.

Medical Officer to Her Majesty's Prisons.—The opinion of the Secretary of State is undoubtedly correct. The Fifth Section of 6 and 7 Will. IV. states unconditionally that a medical officer is not entitled to a fee for making a post-mortem examination or for giving evidence at an inquest. The coroner has the power of deciding where the inquest shall be held. The fact that the inquiry takes place away from the public institution in which deceased died does not entitle a medica man to claim a fee. If he incurs travelling expenses no doubt he would be granted remuneration therefor.

"MATERNAL IMPRESSION ON THE FŒTUS."

To the Editors of THE LANCET.

SIRS,—Observing some discussion on this subject in THE LANCET of March 6th, I venture to give you, out of many such coincidences or impressions which I have seen, the following:—Ten years ago I was called to a baby of eighteen months, whose little finger had been accidentally cut off cleanly at its base with a hatchet by the next youngest brother. Their mother was then a few weeks pregnant, and in spite of my encouragement made up her mind that her future infant would "have something the matter with its hands." On attending her at this confinement I had quite forgotten her fears, thinking at the time that I had allayed them, but her first question immediately on delivery proved to the contrary, and to my chagrin the child had a supernumerary ulnar digit on each hand. There was no family history of such additional fingers, but the woman on a previous occasion had been equally confident beforehand of a "bunch of grapes" which duly appeared as a nævus on the breast. Whatever may be the rationale of these cases, their frequency should make us very careful in the lying-in room not to scout the possibility of such sequence. I am, Sirs, yours faithfully,

Royal Exchange, March 8th, 1897. ROBERT J. COLENSO.

Disgusted.—It would not be wise to publish such a communication. Our correspondent will understand that a medical man must do his duty whatever the consequence, and the letter contains almost a warning to young men to abstain from a proper course of treatment lest misunderstanding should follow.

AN AGREEMENT TO REFUSE PAYMENT BY CONTRACT.

THE Medical Union of Condroz, in Belgium, is apparently better agreed with regard to the interests of its members than is usually the case in less sparsely inhabited districts. A very elaborate tariff has been drawn up giving the extra fee or milage for all villages and hamlets, and no member is permitted to arrange regular hours for consultation anywhere except at his own residence, or to make any special terms with insurance companies or provident clubs. The only reduction permitted is for attendance on paupers, and for such attendance the authorities will have to pay by the visit, which will be charged 25 per cent. less than a visit to an ordinary person.

Q.—These questions can only be answered for certain when a legal decision has shown the reading that the law courts are prepared to put upon the Act. In our opinion B.'s notification would not carry the fee.

J. P.—The statements have been refuted over and over again. But they will continue to be made over and over again, for the holders of these tenets are particularly *Kwaaje* people.

THE PAYMENT OF FEES UNDER THE NOTIFICATION ACT.

To the Editors of THE LANCET.

DEAR SIRS,—Will you please notice enclosed in THE LANCET and give your opinion as to whether a practitioner must go down to the office. It is a loss of about two hours and a half to me going down for the notification fees due me. Surely the city M.O.H. could see that a cheque be sent me. And oblige Yours faithfully,

March 1st, 1897. R. R. RENTOUL.

*** We print Dr. Rentoul's enclosure below, and presume that the footnote authorising the payee to receive his money by deputy escaped Dr. Rentoul's observation.—ED. L.

[ENCLOSURE.]

CORPORATION OF LIVERPOOL.

Municipal Offices, Liverpool,
Treasurer's Office.

.....189

Sir,

You are requested to call at this Office to-morrow between 10-30 and 12 o'clock, to receive payment of your account.

Your obedient Servant,
J. E. A. ROGERS,
Treasurer.

M......

☞ This Circular to be produced at the time of payment, and if inconvenient for you to apply personally, you are requested to fill up and sign the following order:—

Please pay the Bearer, Mr......
.....*account, against the Corporation of Liverpool.*
.....

Sarum.—The terms of the agreement define, or should define, the position exactly. For a term of years a certain share was to accrue to the late owner's son. At the end of that period a new agreement must be made if the partnership is to continue, and the contracting parties must settle between them what the terms shall be for the future. Neither side can claim anything under the terms of an expired agreement, but if the agreement contains provisions for future arrangements, it has not expired. The point is obviously one for amicable arrangement.

Hosted by Google

"ANTISEPTIC MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—I fear Dr. Playfair cannot have read my letter, as had he done so he would not for the second time misquote me. I never said one word about 1 in 2000 of the perchloride of mercury as a disinfectant for the "hands." What I did say was "as a vaginal injection in normal labours, and intra-uterine where the hand, forceps, &c., have entered the uterus." As a matter of fact, I use 1 in 1000 for the hands and 1 in 1000 dissolved in glycerine as a lubricant for both hands and forceps. I have used the latter for years, and beyond a slight staining they have suffered no injury. When Dr. Playfair challenged Dr. Godson's able advocacy for the perchloride treatment we certainly expected something more scientifically definite than his statement that "sufficient creolin should be dropped into the water to be used to make it milky in appearance." Why does he not give us the strength, and, as Mr. R. L. Wood very properly asks, its bactericidal and spore-killing properties? We could then judge for ourselves as to the relative merits of both.

I am, Sirs, yours truly,

Ballincollig, March 15th, 1897. JAMES J. HARDING.

Mr. H. Mynors.—The dissemination of such cards is, of course, most regrettable, but only the bodies from whom the offender holds his degrees or diplomas can interfere with any proper *locus standi*.

AN IMPROVED REEL FOR THREAD.

MR. G. GILMORE STEVENS, of 27, Lochaber-street, Roath Park, Cardiff, has forwarded to us a new form of reel which deserves the attention of all workers with the needle. When a length of thread is taken from a reel it is more often cut off with the teeth than with the scissors, an objectionable practice, which, though it may be excused on the ground of convenience, is injurious to the front teeth and encourages the dangerous habit of holding small objects in the mouth. Mr. Stevens's invention saves the trouble of looking for the scissors and removes any excuse for biting off thread. It is very simple, consisting merely of a single steel edge about a quarter of an inch long, sunk in a notch cut in one of the ends of the reel, and the piece of thread that has been unwound is at once cut off when pulled against it.

B. B. would like information as to the best books to read in preparation for the M.D. Durham examination for practitioners of fifteen years' standing.

"DR. RENTOUL'S EXPENSES FUND."—FOURTH LIST.

To the Editors of THE LANCET.

SIRS,—The total amount to date is £92 17*s.* I now ask with confidence that those supporters of Dr. Rentoul whose support is not limited to words (which are cheap) should at once forward their subscriptions. If this list were some testimonial to a rich and highly placed member of the profession who did not need it, I suppose we should have had to get clerical assistance in acknowledging all the donations. As it is, however, a question of repaying a hardworking practitioner money spent in furthering our interests, it takes nearly three months to raise a paltry sum of £92. This is indeed gratitude, and will doubtless act as an incentive to other men to spend time, money, and health in medico-political work.

I am, Sirs, yours faithfully,

Gateshead, March 16th, 1897. ALFRED COX, M.B. Durh., Hon. Sec.

W. H.—The Local Government Board is not concerned with the qualifications further than that they must be such as entitle their Poor-law officers to be registered as qualified to practise both medicine and surgery. The scheme granting the conjoint diplomas of the Royal College of Surgeons in Ireland and the Apothecaries Hall of Ireland was not closed for new entries until June 30th, 1895, students entered before that date being allowed to complete their examinations.

"THE DOSE OF IPECACUANHA."

To the Editors of THE LANCET.

SIRS,—It may be of interest, in connection with Dr. Balmanno Squire's letter which appeared in THE LANCET of March 13th respecting ipecacuanha wine, to mention that the sample was made from Brazilian root in strict accordance with the pharmacopœial directions, and that the wine contained 0·085 per cent. of alkaloids.

We are, Sirs, yours truly,

Oxford-street, W., March 15th, 1897. JOHN BELL AND CO.

Mr. Robert Reynolds.—To notice these people is only to further advertise them. Those who are deceived by such trash do not read our columns.

MEDICAL FEES IN RURAL FRANCE IN THE LAST CENTURY.

ACCORDING to a paper in the *Journal des Sciences Médicales de Lille* some items are given of the fees obtained by a medical man at Elincourt in the time of Louis XVI. A visit near was 5 sous, but 10 sous if the patient lived in a village at some distance. Persons of distinction, too, had to pay more; thus the prior of a monastery was charged 30 sous every time his wound was dressed, and as this was done twice a day for some five weeks and once daily for fifteen weeks more his reverence must have proved a valuable patient as practice went then. Bleeding was charged 5 sous, but 10 if on the foot, extraction of a tooth was 5 sous, reduction of the clavicle 3 livres, and setting a broken arm 30 livres! *Le Scalpel* publishes some similar information obtained from a medical man whose great-grandparents took their child to a Lille physician, who, being the attendant of the prince bishop, had a very large practice. He stripped the child and examined him most carefully, but all he asked was 5 sous.

A Subscriber of Forty Years appears to us to make out a very good case for superannuation. His medical adviser clearly tells him not to do the work that his duties must entail upon him.

A KNOWLEDGE OF THE ODDS.

WE commend the following incident to the notice of Mr. Hawke as another instance of the evils of a knowledge of the "odds." Scene: the ward of a metropolitan hospital; in one bed is lying a member of the sporting fraternity; to him enter a surgeon, attended by fifteen eager and obsequious dressers. Surgeon, to the dresser of the case, after an able and exhaustive account of the symptoms: "Now, Mr. Smith, would you operate on this case?" Mr. Smith (dresser): "No, sir, I should not." "And you, and you, and you?" indicating the others. Unanimous negative. "Well, gentlemen, you are all quite wrong," says the surgeon, with conscious pride, "I intend to operate." Voice from the bed: "No you don't, gov'nor! Fifteen to one agin it—no chaunce. 'Ere, I say, m ss, give me my clothes; I'm orf."

The Goulstonian Lectures

ON

THE CHEMISTRY AND PATHOLOGY OF GOUT.

Delivered before the Royal College of Physicians of London,

BY ARTHUR P. LUFF, M.D., B.Sc., F.R.C.P. LOND.,

PHYSICIAN IN CHARGE OF OUT-PATIENTS IN ST. MARY'S HOSPITAL, AND LECTURER ON FORENSIC MEDICINE IN ST. MARY'S HOSPITAL MEDICAL SCHOOL.

LECTURE I.[1]

Delivered on March 23rd.

MR. PRESIDENT AND GENTLEMEN,—When I accepted the duty of delivering the Goulstonian Lectures for this year I was deeply sensible of the honour conferred upon me and of the serious responsibility that I incurred. As the youngest Fellow of this College I should, perhaps, not have ventured to discourse to you on the subject of gout—a subject which has been so enriched and so ably dealt with in the past by many distinguished Fellows of the College—were it not that I thought the occasion was a convenient one to briefly review the various opinions held as to the causation and nature of gout, and at the same time to place before you the results of some experimental work that I have been conducting on the chemistry and pathology of this disease. As I propose to continue and extend this line of work I can only in these lectures lay before you the results that I have so far obtained and the conclusions that I have arrived at from those results. I must therefore request your indulgence for the somewhat fragmentary nature of the experimental work.

Gout is the manifestation of a number of morbid tendencies, some of which may be inherited and some acquired, and which result in the different diseases associated with the arthritic diathesis. If the joints are affected articular or regular gout results; if other organs or tissues are affected then irregular gout is produced. Gout is associated with the presence of an excess of uric acid in the blood, and the questions that I propose to discuss in these lectures mainly resolve themselves into the mode or modes by which the uric acid is produced and introduced into the blood, the source or sources of its production, the relationship that it bears to the gouty paroxysm and to the other manifestations of gout, and the factors or conditions which influence its formation and its injurious action.

Of the various theories to account for the production of gout the humoral theories have been to the front for many centuries at various periods in the history of the disease. Galen was one of the first to teach that tophi arose from the desiccation of collected and pathologically altered humours. Cullen, who was the great opponent of the ancient humoral theory of gout in the latter half of the last century, admitted, however, that in some instances a peculiar matter appears in gouty patients, but he considered that it was the effect and not the cause of the malady. Uric acid was discovered in the urine by Scheele in 1775, and in 1787 Wollaston demonstrated its presence in gouty concretions. These discoveries did not, however, bring to light the important part played by uric acid in gout. It was in 1847—just half a century ago—that a distinguished Fellow of this College, Sir Alfred Garrod, first found uric acid in the blood of gouty subjects in the form of a sodium salt. The discovery of uric acid in the blood of gouty patients eventually led to the much discussed question as to whether it was the cause or the result of gout. Those who held the former view were in their turn divided as to whether the uric acid compound only exerted its baneful effects when it had crystallised out of the blood and had become deposited in the affected tissues, or whether while still circulating in the blood it exercised a true toxic influence. The various views held as to the primary cause of gout may be classified into the three following groups: (1) excess of uric acid regarded as the primary cause; (2) morbid changes in the structure of tissues regarded as the primary cause; and (3) nervous disturbance regarded as the primary cause. I propose to briefly pass in review the various opinions held as to the primary causation of gout, adopting the classification just given.

1. EXCESS OF URIC ACID REGARDED AS THE PRIMARY CAUSE OF GOUT.

This group may be divided into two sections accordingly as the uric acid compound is regarded as exerting its baneful effect in the crystalline state or in the dissolved state.

I. *The uric acid compound regarded as acting passively and physically while in the crystalline state.*—Sir Alfred Garrod and Sir William Roberts are the two principal exponents of this view, which regards gout—in so far as its phenomena depend on uric acid—as a disease the manifestations of which are proximately due to mechanical injury. Sir Alfred Garrod holds that every paroxysm of gout is attended by a crystalline deposit of sodium biurate and that this deposit exercises chiefly a mechanical effect. He explains, in connexion with articular gout, that when the blood for some reason or other is incapable of holding the uric acid compound in solution it is deposited in an articular cartilage which is specially predisposed for its reception. Such predisposition is generally caused by its being the seat of former injury or disease. The crystallisation of the biurate within the interstices of the cartilage then provokes the inflammatory changes, so that the deposition is the cause of the inflammation. Sir William Roberts is of opinion that uric acid probably does not possess any inherent poisonous quality and that as long as it remains in solution it produces no harmful results. The mischief that it is capable of producing only results from its precipitation or crystallisation as sodium biurate in the tissues or fluids of the body. He considers that the inflammation, pain, swelling, and the remoter secondary degenerative changes of regular gout are quite explicable by regarding the crystalline urates which are precipitated in the cartilaginous and fibrous structures of the joints as exerting a mechanical action as foreign bodies. He even considers that the manifestations of irregular gout may be due, like the arthritic manifestations, to uratic deposition: that is, to actual precipitation of crystals of sodium biurate into the connective and fibrous structures of the implicated organs, whether the liver, heart, lungs, or brain, or into the fibrous sheaths of the nerves controlling the functions of the affected viscera. Sir William Roberts is further of opinion that the presence in the blood of scattered needles of sodium biurate might constitute foci around which clotting might take place; and that the thromboses not unfrequently observed in gouty cases might thus be accounted for. I shall have occasion to refer later to the various localities in the body, apart from the joints, in which uratic deposits have been found; but as regards the possible deposition of sodium biurate in nervous structures constituting the exciting cause of some of the pains and affections of different viscera peculiar to irregular gout, it may be of interest to mention here the following facts. Crystals of sodium biurate have been found by Watson, Gairdner, and Dafour on the cerebral meninges; by Schröder van der Kolk in the neurilemma of peripheral nerves; and by Cornil in the cerebro-spinal fluid.

With regard to the manifestations of irregular gout being due to uratic deposits in the affected viscera, it is true that observations on the subject are very limited in number. But in the first place it should be remembered that such irregular uratic deposits are extremely likely to escape observation in the post-mortem room unless very carefully looked for by the aid of the microscope; and in the second place it is highly probable that such deposits would become dissolved during life, as the attack of irregular gout passes off. Cornil and Ranvier also favour the idea that the crystalline uratic deposit in cartilages produces inflammatory changes by its mechanical irritation.

The question might be raised that if the crystalline biurate always acts as an irritant, why should not the semi-solid urinary excrement of birds and serpents set up kidney mischief by acting as an irritant to the kidneys during its excretion. The reason is that the urinary excrement of birds and serpents is composed of an amorphous quadriurate, and that in the amorphous condition it is incapable of acting as an irritant. Moreover, it is possible, as Sir William

[1] Lecture II. was delivered on March 25th, and Lecture III. will be delivered on March 30th, 1897.

Hosted by Google

Roberts has suggested, that the uratic excrement passes through the tubules of the kidneys of birds and reptiles in the gelatinous form, which could not produce the mechanical irritation that a crystalline deposit would be liable to cause.

II. *The uric acid compound regarded as acting as a poison or irritant while in the dissolved state.*—This view, while holding that the uric acid compound is the primary cause of gout, regards it as producing morbid changes in the structure of tissues while remaining in the dissolved state. Many writers and observers have supported the view that, apart from the local trouble in the joints caused by the deposited sodium biurate acting as an irritant, the soluble uric acid compound which is circulating in the fluids of the body acts as a poison, the toxic effects of which are responsible for a number of the symptoms associated with the gouty state. Pfeiffer holds the somewhat peculiar view that a compound of uric acid is deposited in both healthy and diseased portions of the body—apparently without producing any marked symptoms—and that an acute attack of gout is caused by the blood re-dissolving this deposited uric acid compound owing to a temporary increase in the alkalinity of the blood, and that dissolved in the blood in this concentrated form the uric acid compound acts as a chemical poison. That this view is untenable is evident when it is remembered that uric acid is deposited as the sodium biurate, and, as will be shown later, the solubility of this body in a fluid medium is not heightened by an increased alkalinity of that medium. Sir William Roberts[2] argues that the acceptance of the theory that uric acid possesses a toxic action is difficult for the following two reasons: (1) that there is no direct experimental proof that uric acid is a toxic agent; and (2) that although the fluids of the body of a gouty man on the eve of an outbreak of acute gout are impregnated with sodium biurate to saturation, yet such a person does not show any signs of poisoning, but enjoys complete immunity from toxic symptoms until the sudden advent of the arthritic attack. Another fact which is strongly opposed to the view that uric acid is a toxic agent is that in cases of leucocythæmia and severe anæmia the blood is frequently highly charged with uric acid without the production of any toxic symptoms that could be referred to the uric acid.

Kolisch[3] considers that some antecedents or allies of uric acid are responsible for the toxic effect which he believes constitutes the primary cause of gout. His view is that the graver manifestations of gout only make their appearance when the functions of the kidneys become impaired from any cause, and since he finds that in the urine of the gouty there is an increase of alloxuric substances, and also that alloxur bases cause changes in the kidneys resembling parenchymatous degeneration, he infers that these bases are concerned in the production of the kidney affection which precedes the development of gout. His theory is that during normal action of the kidneys the greater part of the alloxur bases is excreted as uric acid; but when the structures which form uric acid are enfeebled there is an increased excretion of alloxur bases with concomitant toxic effects. Kolisch's views have received some confirmation by Weintraud,[4] who has also found an excessive excretion of alloxuric substances in the urine of gouty patients. On the other hand, they are controverted by Schmoll,[5] who in one case of chronic gout did not find any increased excretion of alloxuric substances.

2. MORBID CHANGES IN THE STRUCTURE OF TISSUES REGARDED AS THE PRIMARY CAUSE OF GOUT.

This group may be divided into two sections accordingly as the morbid changes are produced by the presence of a soluble urate or not.

I. *Necrotic changes in the affected tissues regarded as the primary cause of gout, the necrosis being due to the presence of dissolved urates.*—Ebstein,[6] who has devoted a considerable amount of time to the experimental study of the causation of gout, is the great exponent of this view. His theory is that a destructive or, as he terms it, a necrotising process is produced in the cartilages or other implicated tissues by uric acid in one form of combination, and that following this the uric acid in another form of combination is deposited in the necrosed areas. In other words, that a destructive process always precedes the process of deposition, both processes being due to uric acid, but in different states of combination. Ebstein maintains that uratic crystals only form in necrotic tissues—never in healthy tissues. He regards the necrosis of tissue and the subsequent uratic deposits as together constituting the characteristic *ensemble* of the gouty process. His theory assumes that the irritant is the neutral sodium urate in the dissolved state, and that the first step in the gouty process consists in a stasis of the lymph stream, followed by the infiltration of the tissue in circumscribed areas by the lymph containing the dissolved neutral urate. The neutral urate, according to his view, acts as a chemical irritant, and sets up a necrotising process in the implicated tissues, and finally produces complete necrosis of the tissues in the affected areas. The necrotising and necrotic portions of the tissues provoke irritation of the surrounding parts and so produce the inflammatory phenomena of gout. Ebstein assumes that the process of necrosis generates a free acid, which converts the neutral urate present in the fluids of the body into the acid urate, which substance is then deposited in the crystalline form in the fully necrosed areas. No mention is made of the nature or name of this hypothetical acid. In support of this theory Ebstein depends upon two different classes of experiments that he performed. One class consisted of his examination of the organs and tissues of birds that he considered he had rendered gouty by preventing the elimination of their urinary secretion. The other class of experiments consisted of observations on the irritant effect of a solution of a sodium urate on the delicate corneal tissue of the eye. As I venture to differ from the deductions that Ebstein has drawn from his experiments and observations, I propose to describe his methods of experimentation and to briefly criticise his deductions therefrom.

Ebstein's first series of experiments consisted in an endeavour to induce in cocks a condition which, from the anatomical point of view, he considered was analogous to the gouty state in man. This he effected by preventing the elimination of their urinary uratic secretion in two ways—(*a*) by ligaturing the two ureters and so damming back upon the circulation the urates which would otherwise have passed away; and (*b*) by administering to the cocks small and repeated subcutaneous injections of the neutral potassium chromate, which Ebstein considers inhibits the passage of uric acid through the kidneys by its action on the renal parenchyma, and so causes a damming back upon the circulation of a portion of the urates which normally are excreted in their entirety by the kidneys. In the bodies of the birds experimented on uratic deposits were found in the articulations, in the tendon sheaths, in the liver, and in the muscular tissues. Ebstein found that the deposition of urates was much more copious and more widely spread in the cocks experimented on by injection of potassium chromate than in those whose ureters were ligatured. This difference he referred to the fact that he could keep the birds alive for a long time while subjecting them to the action of potassium chromate, whereas after ligaturing both ureters they as a rule only lived for about twenty-four hours. As the result of these experiments Ebstein came to the following conclusions: (1) that necrosing and necrotic processes are developed in various organs as the result of some irritant; (2) that uratic deposits form in the necrotic areas which in appearance resemble the gouty deposits of man; and (3) that a reactive inflammation, with infiltration of small cells, is set up in the neighbourhood of these necrotic areas. This class of experiments, therefore, consisted of observations of the uratic deposits formed in fowls when the elimination of their uric acid is prevented, either by ligaturing the ureters or by the progressive disablement of the kidneys by repeated subcutaneous injections of potassium chromate. I do not think that the morbid processes occurring under these conditions in fowls can be considered as in any sense comparable with those occurring in connexion with gout in man. Ebstein found uratic deposits in the liver and muscular tissues of the birds experimented on, localities where they are not found, at all events to any appreciable extent, in human gout. From this one may fairly conclude that the two processes cannot be considered as comparable. Moreover, since the fowl produces and eliminates by the kidneys so large a quantity of urates, the more or less sudden stoppage of kidney excretion must necessarily result in the damming back of it and its rapid accumulation in the blood and tissues, where, as Sir William Roberts[7] suggests, it would probably first collect in a state of solution as the quadriurate, which would then be precipitated in

the tissues as the gelatinous biurate, and this in its turn would be changed into the crystalline biurate.

It is on the second class of experiments that Ebstein depends for his assumption that the neutral sodium urate is capable of acting as a chemical irritant to the tissues and of producing in them the necrotising changes which subsequently lead to complete necrosis of the affected areas of the implicated tissues. In order to show that a combination of uric acid with sodium acted as an irritant Ebstein took a saturated solution, prepared at 100° F., of uric acid in a 5 per cent. solution of sodium phosphate and injected it into the peritoneal cavity, into the kidney, into the anterior chamber of the eye, into the cartilage of the ear, and into the cornea of a rabbit. Powdered uric acid was also introduced by insufflation into the conjunctival fold of one eye. Very appreciable changes were produced in the cornea only, and it was in this structure that Ebstein studied what he considers were the irritant or toxic effects of uric acid. He found that these injections produced a modified form of inflammation in the tissues of the cornea. As a control experiment he injected into the cornea of the other eye a simple solution of sodium phosphate, or water containing calcined magnesia in suspension, neither of which produced any inflammatory changes. He therefore inferred that the inflammatory changes were set up in the cornea by the urate in solution acting as a chemical irritant.

The objection to this method of experimentation is that, in the first place, the solution of uric acid in sodium phosphate does not contain the neutral sodium urate, which is the body on which Ebstein relies for the production of the initial irritant effects leading on to the necrotising process. The solution would contain the sodium quadriurate or the biurate, or a mixture of the two. Moreover, as Sir William Roberts has pointed out, such a saturated solution would soon begin to deposit its urate in the form of the gelatinous biurate, which, infiltrating the affected area of the corneal tissue, would act as a mechanical irritant. It is therefore clear that all the corneal changes observed by Ebstein can be accounted for by the assumption that they are caused by a mechanical irritant. The experiments of Neubauer are opposed to the view that a soluble urate circulating in the blood can act as a poison or irritant and start necrosis. He found that the administration of large quantities of uric acid to rabbits (as much as twelve grammes in some cases) did not seem to cause any inconvenience. Moreover, is it likely that solutions of urates should act as irritants when their passage through the kidneys is part of the natural elimination of nitrogen in man? If solutions of the urates are to be regarded as irritants then the kidneys would never escape damage. Another important argument which militates against the acceptance of Ebstein's theory is that not only is there no proof that the neutral sodium urate, upon which he depends for the starting of the gouty changes, ever exists in the human body, but, on the other hand, there is strong evidence to show that it never can exist in the human body. The neutral sodium urate is an extremely caustic and unstable body, and is decomposed in the presence of carbonates, so that it is impossible for it to exist in the blood. The first factor upon which Ebstein relies for his theory of the causation of gout therefore disappears. Moreover, the responsibility for the assumed necrotic changes cannot be transferred from the neutral sodium urate to the biurate, since Pfeiffer has shown, by means of subcutaneous injections of a solution of a biurate, that although it can produce pain and irritation, yet it cannot cause necrosis, especially when in so weak a solution as must occur in the human body. The assumption by Ebstein, that the process of necrosis generates an acid, which is supposed by him to convert the neutral urate into the acid urate, is based on an imperfect acquaintance with the chemistry of the urates. Sir William Roberts has shown that uric acid is primarily taken up by the blood and lymph as a quadriurate, not as a neutral urate, and he has also proved that the formation and deposition of the crystalline biurate are not favoured by the intervention of an acid. Moreover, in connexion with leucocythæmia, severe anæmia, and other diseases to which reference will be made later, we know that a considerable quantity of uric acid may be present in the blood without giving rise to necrosis of tissues anywhere.

Ebstein considers that by dissolving out the crystalline urates from tissues in which they are deposited he is able to demonstrate the existence of necrosis in the sites previously occupied by the uratic deposit, and insists that the crystalline urates are only deposited in tissues that have undergone necrotising and necrotic changes. This, however, is opposed to the experience of such competent observers as Sir Alfred Garrod, Sir William Roberts, Sir Dyce Duckworth, and Cornil and Ranvier. I have also frequently examined sections of cartilages containing uratic deposits which have not shown any necrosis at the sites of the deposits and in which the cartilage appeared to be practically uninjured. The changes that may be seen in cartilages containing a dense deposit of sodium biurate are quite intelligible on the assumption that they are caused in part by the mechanical pressure of the crystals, and in part by the inflammation and subsequent degeneration set up by the presence of the crystalline deposit. If the sodium biurate is only formed and deposited in necrosed areas, how is it that crystals of sodium biurate are occasionally found free in the synovial fluid of a gouty joint? As Sir William Roberts[8] remarks: "It will scarcely be contended that necrotising and necrotic processes can take place in synovia!"

Sir Dyce Duckworth[9] in a modified sense believes that a soluble urate may act as an irritant. Although he considers that gout is primarily due to a disorder of the nervous system, he entertains the additional view that the urate in solution may set up degeneration and necrotic changes in tissues. This view is expressed as follows: "It can hardly be doubted that lesions result from the action of uric acid in solution in the tissues, and that thus both acute and chronic inflammatory changes may be set up without the direct influence of uratic deposit as an alleged irritant in joints and in certain viscera, notably in the kidneys. Degenerative changes and necrosis also appear to be thus induced."

II. *Inflammatory or degenerative changes in the affected tissues regarded as the primary cause of gout, such initial changes not being caused by urates.*—Dr. Ord in 1872 considered that gout was due to a special form of degeneration in some of the fibroid tissues, resulting in an excessive formation of sodium urate, which is then discharged into the blood, and is subsequently deposited in those parts least freely supplied with vascular and lymphatic structures. Dr. Ord, whose views in this particular have been supported by Dr. Norman Moore and Mr. Bowlby, also considers that uratic deposits only occur in tissues which have previously begun to degenerate. Dr. Berkart[10] considers that the severity of the local symptoms attending an attack of acute gout are inconsistent with the assumption that they are produced by a primary chondritis, due to irritation set up by the deposition of sodium biurate in the articular cartilages. He considers that the *rôle* of the uric acid is one of a humbler kind than that which has hitherto been attributed to it. In his opinion the uratic deposits are most frequently connected with a form of panarthritis which chiefly affects the smaller joints of the extremities. Without assuming any identity between arthritis deformans and gout, he considers that in both instances the disease probably originates in some kind of atrophy of the substance of the bone, that the degenerative process then attacks the cartilages and fibrous tissues of the joints, and that following on this there occurs a necrosis of the tissues close to or within the joint. This necrosis he considers is the primary cause of the pain, hyperæmia, collateral œdema, and desquamation of the skin of the affected joint. The degeneration and necrosis of the tissues are the result of a profound disturbance of nutrition. Dr. Berkart attributes the presence of the urates in the blood in part to leucocytosis and in part to the formation of uric acid from the disintegration of the tissues; so that he regards the uratic deposits as an epiphenomenon, and not as the cause of the gouty paroxysm.

3. Nervous Disturbance Regarded as the Primary Cause of Gout.

The view that gout is intimately connected with disturbances of the nervous system has many supporters. Cullen, the great opponent of the humoral theory in the latter half of the last century, considered that gout mainly depended on an affection of the nervous centres. Sir Dyce Duckworth,[11] while accepting the view, as previously mentioned, that uric acid has some connexion with gout, considers that gout is primarily dependent on a functional disorder of a definite tract of the nervous system, and that the part specially involved is possibly situated in the medulla oblongata, where it may be that there is a trophic centre for the joints. One reason that Sir Dyce Duckworth gives for considering this possible is the relationship of gout to diabetes,

the consideration of which has led him to the belief that the portions of the nervous system involved in the two diseases cannot be far apart from one another. In consequence of this disorder of the neuro-trophic system defects of nutrition arise, which not only cause undue formation of uric acid, but also inhibit the normal destruction of that body in the tissues; at the same time the renal excretory power for uric acid appears to be temporarily inhibited as part of the process of the gouty paroxysm. Sir Dyce Duckworth therefore regards gout as belonging to the class of neuro-humoral diseases, but he does not at present insist on the localisation of the primary disturbance in a limited portion of the cerebro-spinal axis. He draws the following distinction between inherited and acquired gout. In primary, or inherited, gout the toxæmia is dependent on the inherited gouty neurosis. In secondary, or acquired, gout the toxæmia arises from the digestive and excretory organs becoming overloaded, and then, if with this toxæmia there are depression and exhaustion of the nervous system the gouty neurosis may be established by the morbid blood condition affecting the nutrition of the nervous system. Sir Dyce Duckworth claims that the suddenness with which an acute attack of gout comes on, preceded as it usually is by a sense of well-being in the patient, is indicative of the nervous origin of the outbreak, and that it is to the instability and undue sensitiveness of the nervous system in the gouty that the manifestations of the paroxysm are due.

Dr. Edward Liveing[12] considers that there is much to be said in support of the view that gout is the manifestation of a disorder which has its primary seat in the nervous system. He remarks that the view that the uric acid exerts a toxic influence upon the nervous centres and that the particular character of the disorder is determined by the territory involved is one that presents real obstacles, on account of the limited operation attributed to a cause so general in its nature.

Dr. P. W. Latham[13] regards some change in the nervous system as the most important factor in the etiology of gout. He thinks that such change is localised in the medulla oblongata, or in the spinal cord, or in both, and that this nervous disorder may be either hereditary or acquired. He argues that if a portion of the medulla oblongata involving some of the roots of the vagus be the part affected, the metabolism of the liver may be interfered with, and so lead to the formation of uric acid. He also considers that if from any cause uric acid is circulating in the blood it would act as a poison upon any weak spot in the nervous system, and that it is intelligible that it might act upon portions of the spinal cord, which control the nutrition of the joints, and so cause nutritive changes or inflammation in the joints connected with that portion of the cord. In consequence of the inflammation or nutritive changes in the joints sodium biurate becomes deposited in them, or in the tissues around the affected joints. Dr. Latham explains the phenomena of a gouty paroxysm by direct stimulation of sensory nerves by uric acid. He considers that the gout associated with chronic lead-poisoning may be explained by the lead acting in such cases more particularly on those portions of the spinal cord which are concerned in gout.

Dr. Ralfe held the view that the accumulation of uric acid in the blood in gout was due to non-conversion into urea of the uric acid normally formed in the tissues, and he considered that the conditions which prevent the normal destruction of uric acid in the tissues depend probably on disturbance of innervation.

From a careful consideration of these various views as to the primary cause of gout I am of opinion that the greatest mass of evidence is in favour of the view that a compound of uric acid is the *materies morbi*.

The next question to consider is whether the excess of uric acid in the blood in gout is the result of deficient excretion, of over-production, or of deficient destruction. All observers are agreed that an abnormal quantity of uric acid is found in the blood in gout. This overcharging of the blood with uric acid must be due to one or more of the following causes: (1) normal production and deficient excretion of uric acid; (2) over-production and normal excretion of uric acid; and (3) diminished destruction of uric acid by imperfect oxidation or by some other means.

This last theory may be dismissed at once. There is no proof that the process of oxidation destroys uric acid; on the contrary, there is proof that uric acid is produced by a process of oxidation. Moreover, not only is there no proof that uric acid is produced during health in the organs and tissues of the body generally and that it subsequently undergoes more or less destruction, but there are good reasons for believing that uric acid is in health only formed in the kidneys and never appears in the general circulation except under pathological conditions.

With regard to the second theory—of over-production and normal excretion of uric acid—there is abundant experimental proof to show that an increased production of uric acid does not lead to gout so long as the kidneys remain in a normal condition. For instance, in connexion with diseases such as leucocythæmia and severe anæmia there is an over-production of uric acid, but no development of gout. In these diseases the excessive quantity of uric acid produced is readily excreted by the kidneys, as is shown by the large amounts of uric acid that may be found in the urine. In addition, gout is essentially a disease of middle age, and is only very exceptionally met with in childhood and in youth, although the formation of uric acid is greatest in early life, and apparently diminishes with the advance of age.

View that deficient excretion of uric acid is connected with gout.—There are many facts to support the view that gout is due to deficient elimination of the uric acid normally produced, and to subsequent absorption of this uric acid from the kidneys in consequence of that deficient excretion. That there is a deficient excretion of uric acid in gout is, I think, justified by the following facts. Judging as far as is possible by averages, recent accurate estimations of the excretion of uric acid show that in gouty subjects there is a decrease in its daily excretion as compared with healthy individuals. Pfeiffer[14] compares the quantities of uric acid contained in the urine of gouty patients at various ages and in whom the complaint had not yet become chronic with the quantities contained in the urine of healthy subjects at the same age. For purposes of comparison the quantities of uric acid found by him were calculated in grammes per 100 kilogrammes of the body weight. His results are given in the following table:—

Age.	Gouty subject.	Healthy subject.
30 to 40 years	0·885 grm.	0·965 grm.
40 to 50 ,, ...	0·818 ,,	0·882 ,,
50 to 60 ,, ...	0·701 ,,	—
60 to 70 ,, ...	0·661 ,,	0·752 ,,

This table indicates that the amounts of uric acid excreted by gouty subjects were always rather lower than the quantities excreted by healthy persons of the same age.

In the following table (Table I.) are the results of the daily determinations that I made for eight successive days respectively of the total uric acid excretion in the urine of three persons—viz.: (*a*) a male patient suffering from an attack of sub-acute gout supervening on chronic gout; (*b*) a male patient suffering from chronic gout and lead poisoning, with recent pain in the right metatarso-phalangeal joint and in both ankle-joints; (*c*) a healthy man. The quantities of uric acid in the three cases are given in grammes and are calculated per 100 kilogrammes of the body weight. All the individuals were between forty and fifty years of age.

TABLE I.—*Showing the Daily Elimination of Uric Acid in* (a) *a Case of Sub-acute Gout;* (b) *a Case of Chronic Gout and Plumbism;* (c) *a Healthy Person. Quantities of Uric Acid given in Grammes per 100 Kilogrammes of the Body Weight. All the individuals between Forty and Fifty Years of Age.*

Sub-acute Gout.	Chronic Gout.	Healthy Subject.

These results, I think, justify the view that deficient excretion of uric acid occurs in connection with gout. I shall have occasion in a subsequent lecture to discuss in detail the probable *rôle* taken by the kidneys in the production of uric acid, and in the development of gout.

Estimation of uric acid in urine.—One of the lines of investigation that I have pursued required that a very large number of estimations of the total amount of uric acid excreted in the urine per diem should be made. The process that I have employed throughout is the Gowland Hopkins method, which I consider is a very accurate and reliable process. I have had a very considerable practical experience of the various methods that have been employed for the estimation of uric acid in the urine, including Heintze's process, Haycraft's process, Fokker's process, Salkowski's process, and Ludwig's modification of Salkowski's process. In connexion with all these processes there are faults or objections from which the Gowland Hopkins process is free. As this method is not employed to the extent that, I believe, it deserves to be, I will briefly describe the process as given by Gowland Hopkins.[15] This process depends upon the fact that when urine is saturated with ammonium chloride all the uric acid is precipitated as an ammonium urate. From the ammonium urate the uric acid is set free and the amount of it is determined by titration with a standard solution of potassium permanganate. One great advantage of this process is that there is no danger of the reduction of the ammonium urate as there is of the silver urate produced in some of the other processes; moreover, the ammonium urate is easy to filter and permits of the liberation of its uric acid with great readiness. Another great advantage of the process is that although xanthin is at first precipitated along with the ammonium urate, yet the subsequent treatment with hydrochloric acid entirely removes it, so that finally it is not estimated along with the uric acid. The details of the process are as follows.

The Gowland Hopkins method for the estimation of uric acid in urine.—To 100 c.c. of the urine powdered ammonium chloride is added till practical saturation is obtained. About thirty grammes of ammonium chloride, as a rule, are required. When a small quantity remains undissolved after brisk stirring for a few minutes saturation is sufficiently complete. The urine is then allowed to stand for two hours, during which time, if possible, it is occasionally stirred to promote subsidence, and is then filtered through thin filter-paper and washed three or four times with a saturated solution of ammonium chloride. The filtrate should remain perfectly clear and bright. The precipitated ammonium urate is then washed off the filter into a small beaker with a jet of hot distilled water, and is heated just to boiling with an excess of hydrochloric acid. The beaker and its contents are allowed to stand in the cold for two hours, when the uric acid separates out completely, and is then collected on a filter and washed with cold distilled water. The filtrate should be measured before the washing is begun, and one milligramme added to the final result for each 15 c.c. of filtrate present—this need never be more than from 20 to 30 c.c. The uric acid is then washed off the filter with hot water, warmed with sodium carbonate till dissolved, and made up with water to 100 c.c. The liquid is then transferred to a flask, 20 c.c. of strong pure sulphuric acid are added, and the mixture is immediately and while warm titrated with one-twentieth normal potassium permanganate solution. The latter should be added slowly towards the end of the reaction, the close of which is marked by the first appearance of a pink colour, which is permanent for an appreciable interval. Previously the disappearance of the colour is instantaneous. The permanganate solution is made by dissolving 1·578 grammes of pure potassium permanganate in a litre of distilled water—1 c.c. = 0·00375 gramme of uric acid.

Estimation of uric acid in blood.—Another line of investigation that I have pursued has involved the examination of the blood of man and of several of the lower animals for the presence of uric acid. Quantitative determinations of uric acid in blood have been made within the last few years by Salkowski and Leube, von Jaksch, and Klemperer. Salkowski and Leube[16] slowly added the fluid blood to ten times its volume of boiling water, boiled for ten minutes, allowed to subside, filtered, and evaporated down to the volume of the original blood used. The uric acid was then determined in this liquid by the Salkowski method. Von Jaksch[17] diluted the blood (using from 100 to 300 c.c.) with from three to four times its volume of water on the water bath, and when coagulation commenced acetic acid was added so as to produce weak acidity; the mixture was then heated in the water bath for from 15 to 20 minutes till the albumin settled, and was then filtered and the sediment extracted and washed with hot water. The filtrate was further acidified with acetic acid, boiled, cooled, filtered, and sodium phosphate added. The Salkowski-Ludwig method for the estimation of uric acid was then employed. Klemperer[18] diluted the blood with from six to eight times its volume of water, removed the albumin by von Seegen's method, and then estimated the uric acid by the Salkowski-Ludwig process.

In order to test the accuracy of the different methods for the estimation of uric acid in blood a quantity of fresh bullock's blood—which I proved to be free from uric acid—was taken, and to it a known percentage of uric acid was added. I then experimentally tried on different batches of this blood the various methods that have just been described. I obtained, however, such very erroneous and discordant results that I was forced to the conclusion that no reliable process had as yet been devised for the estimation of uric acid in blood. I therefore endeavoured to devise a process that would yield reliable results. After performing a very large number of experiments, into the details of which it is unnecessary to go, I arrived at the following process, which constitutes the most reliable one for the estimation of uric acid in the blood with which I am acquainted.

Process for the estimation of uric acid in the blood.—The fresh blood is allowed to flow direct into its own volume of rectified spirit containing 2 per cent. of formalin, with which it is thoroughly agitated; the mixture is then evaporated on the water bath until the mass can be reduced to a coarse powder, which is dried in the water oven and afterwards finely powdered. The admixture of the blood with the spirit precipitates the albuminous matters in a granular form, so that when dried the blood can be reduced with ease to a fine powder; the presence of the formalin prevents any decomposition of the blood in the event of its not being convenient to work it at once to the solid state. For the experimental work one part of the dried blood was taken as being equal to five parts of liquid blood. For the extraction and estimation of uric acid in the blood from 50 to 100 grammes of the powdered blood should, if possible, be taken. In all my analyses of the blood of animals and birds I employed 100 grammes of the dried blood, and in my analyses of human blood I used 50 grammes of dried blood. The method that I employed was to mix 100 grammes of the powdered blood with a litre of boiling distilled water and to allow the mixture to boil for half an hour, during which time it was frequently agitated. It was then filtered, firstly through glass-wool and afterwards through filter-paper, and evaporated down to 50 c.c.; this liquid was filtered, allowed to cool, and then submitted to the Gowland Hopkins process for the estimation of uric acid. On adding known quantities of uric acid to different specimens of blood—which I had previously proved to be free from uric acid—and then submitting them to this process I was able to extract from 80 to 87 per cent. of the uric acid, but I could never get the whole of the uric acid out of the blood residue. I tried various solvents in place of the distilled water, such as dilute solutions of sodium acetate, potassium acetate, sodium phosphate, borax, sodium carbonate, &c., in the hope of being able to extract all the uric acid from the blood, but I was unable to find any solvent that acted better than the distilled water. This process that I have just described is the one that I have employed, in conjunction with the murexide test, in all the examinations of the various kinds of blood for uric acid to which I shall subsequently refer.

Admitting that an excess of uric acid in the blood and that its deposition therefrom in cartilages and other tissues is the direct exciting cause of a gouty paroxysm, the two questions that naturally arise in the mind are: (1) Where is the uric acid formed? and (2) How is the uric acid formed? I believe that uric acid is formed in connexion with some diseases—notably blood diseases accompanied by leucocytosis—in a different manner to that in which it is produced in health, and also in different organs. I also hold the opinion that the source of the uric acid contained in the blood in gout is the same as that from which the uric acid eliminated

in the urine in health is derived. I propose, therefore, to first consider the various views as to the seat or seats of formation of uric acid in health and in gout.

SEAT OR SEATS OF FORMATION OF URIC ACID IN HEALTH AND IN GOUT.

View that the kidneys form as well as excrete uric acid.—Until 1847 it was supposed that uric acid was formed in the kidneys themselves, as up to that time none had ever been detected in the blood. In that year Sir Alfred Garrod showed the presence of uric acid in the blood of gouty subjects, which discovery led to the conclusion that uric acid was formed in certain other organs and tissues of the body, and was merely eliminated by the kidneys. The view that then arose was that the uric acid eliminated in the urine originated in the system by the metabolism of the nitrogenised tissues, and was then thrown out by the kidneys. Sir Alfred Garrod[19] originally held this view, but in later years he came to the conclusion that uric acid is produced by the direct action of the kidneys from urea and other nitrogenised bodies contained in the blood. From the experimental evidence that he has put forward Sir Alfred Garrod[20] concludes that the presence of uric acid in the blood, provided it is not introduced *viâ* the alimentary canal, must be accounted for by absorption into the blood from the kidneys after its formation in these organs, the salt being changed by the blood from ammonium urate to sodium urate. He therefore concludes that uric acid is normally formed in the kidneys, and that when present in the blood it is a result of its having been absorbed after formation in other organs. Kolisch[21] regards the kidneys as the most important of the uric acid forming organs. Dr. Latham considers that the final formation of uric acid takes place in the kidneys, where it is produced by the conjugation of substances manufactured in the liver and conveyed in the blood to the kidneys. The following experimental evidence has been put forward in support of the view that uric acid is formed in the kidneys. Zalesky experimented on serpents, who eliminate all their urinary nitrogen as uric acid. He found that after the removal of the kidneys of serpents they lived about as long a time as when the ureters were tied, and that after death no uratic deposits were found in any of the tissues. As he found after ligaturing the ureters of other serpents that uratic deposits were to be seen after death in most of the organs and tissues, he concluded that the kidneys were the producers as well as the eliminators of uric acid. The following experiments also are strongly opposed to the view that the kidneys, with regard to uric acid, merely act as filters which separate the uric acid brought to them in the blood. Sir Alfred Garrod[22] gave from fifteen to thirty grains of potassium urate daily and similar daily doses of sodium urate without producing any increase of uric acid in the urine. Wöhler and Frerichs found that the administration of potassium and sodium urates increased the amount of urea, but did not augment the quantity of uric acid in the urine. Neubauer found that the administration of large quantities of uric acid to rabbits, either by the stomach or by injection into the veins, was followed by a corresponding increase in the excretion of urea, but no uric acid was discovered in the urine.

View that the liver and spleen produce uric acid.—The view that the liver was the seat of the production of uric acid probably originated in the knowledge that the excretion of uric acid in the urine is most abundant during digestion, when the liver is most active. This view is, however, equally compatible with the idea that the liver merely produces the antecedents of uric acid, which subsequently become conjugated in the kidneys. The investigations of Schröder and Minkowski apparently were strongly in favour of the view that uric acid was formed in the liver. Schröder[23] states that the liver of birds contains a high percentage of uric acid, and that after removal of the kidneys uric acid continues to be formed and accumulates in the liver and blood. The last mentioned statement is utterly opposed to the results of Zalesky's experiments on the extirpation of the kidneys of serpents. Moreover, if the liver of birds contained uric acid, and if it passed thence to the kidneys, it must be present in the blood. As I shall shortly show, the blood of birds is quite free from uric acid. Minkowski[24] succeeded in keeping geese alive from six to twenty hours after extirpation of the liver. After the operation their urinary excrement contained only from 2 to 3 per cent. of uric acid, instead of the normal 60 or 70 per cent. These results are, however, equally compatible with the view that the liver is the seat of production of the antecedents of uric acid.

Dr. Murchison regarded the liver as the seat of production of uric acid, and the presence of the latter in the blood or tissues as the result of functional derangement of the liver, as the result of which the metabolism of some of the albumin is arrested at the stage of uric acid formation instead of going on to the complete stage of urea formation. Charcot regarded the liver as the principal seat of production of uric acid. He considered that a functional derangement of the liver caused the production of excessive quantities of uric acid and its consequent accumulation in the blood. Meissner regards the liver of fowls in the normal condition as the principal source of uric acid, but considers that the spleen and the nervous tissues share in the formation. Ranke was of opinion that his experiments led to the conclusion that the spleen was the principal organ concerned in the production of uric acid. It has, however, never been possible to show that the spleen takes any active part in developing gout. On the contrary, the large amount of uric acid found in the blood in cases of leucocythæmia and severe anæmia show that an exaggerated production of uric acid does not by itself exert any influence on the origin of gout.

Views that uric acid is produced in various tissues.—Ebstein, who attributes in cases of gout the main production of uric acid to the muscles and bone-marrow of the affected extremities, admits, however, that the kidneys may take a part not only in the secretion, but also in the manufacture of uric acid. Robins was the first to formulate the view that uric acid is formed in connective tissues generally, and that the pathological condition is merely an exaggeration of the physiological one. This view, therefore, regards normal fibrous tissue as the seat of production of uric acid, and considers that in gout this production is increased. Chrzonsczewsky also concludes that uric acid arises in connective tissue, and that it is conducted thence through the lymphatic vessels. Cantani considers that the connective tissues take an active part in the formation of uric acid, and that in cases of gout it is especially produced in the cartilages and peri-articular tissues (ligaments, tendons, &c.). Senator also inclines to the opinion that at least part of the uric acid is formed in cartilaginous tissue. Most writers and observers on the subject, however, consider that it is only certain that uric acid deposits in substances of the connective tissue class, and that there is no proof that uric acid is formed in connective tissue. Dr. Haig claims that, in addition to the formation of uric acid in the animal economy, the introduction of small quantities of uric acid in the food leads to its gradual accumulation, and that consequently very large amounts may be stored in the body without any excessive formation having taken place. Dr. Haig, however, does not produce any proof that uric acid is stored up in the system apart from gout. The contrary is proved by the fact that in diseases such as leucocythæmia, severe anæmia, &c., although large quantities of uric acid are formed, yet they are readily eliminated without being stored in the system.

It will be evident that if the various views as to the formation of uric acid in the liver, spleen, connective tissues, muscles, and bone-marrow be correct, then it must be conveyed in the blood in order to be excreted by the kidneys. We know that some 400 to 500 grains of urea are normally excreted in the urine, and that this urea is conveyed in the blood from various organs to the kidneys, where it is excreted; but in addition from eight to ten grains of uric acid are daily excreted in the urine of man. The question is, Does this uric acid come as such to the kidneys? In other words, Is it produced in any of the organs or tissues of the body generally and conveyed in the blood to the kidneys, to be by them excreted; or is it produced in the kidneys and then turned into the urine? The answers to these questions will depend very much upon our ascertaining whether uric acid exists in the blood of man in health, and whether it exists in the blood of those animals, such as birds, the whole of whose nitrogenous urinary excrement consists of a compound of uric acid.

Does uric acid exist in the blood of man in health?—Sir Alfred Garrod,[25] as the result of his investigations, declares that in absolute health the uric acid in the blood is inappreciable, that in gout the blood is very rich in it, and that uric acid is found in smaller but appreciable quantities in individuals who are developing a gouty condition, or who are under the poisonous influence of lead. Von Jaksch[26] examined the blood of several healthy individuals, but found no uric acid present. Klemperer[27] also was unable to find any uric acid in the blood of healthy persons. I have also carefully examined the blood of healthy subjects by the process previously described and have been unable to find any uric acid present.

Does uric acid exist in the blood of mammals other than man?—Sir Alfred Garrod[28] examined the blood of the ox, sheep, and pig by the uric acid thread test, but could never find a trace of uric acid present. I have also examined the blood of the ox and sheep, working on very large quantities of blood by the process I have described, but I have never found any uric acid present.

Does uric acid exist in the blood of birds and reptiles which eliminate all their urinary nitrogen as a compound of uric acid?—Sir Alfred Garrod[29] examined the blood of the turkey, fowl, pigeon, and duck by the uric acid thread test, but never found a trace of uric acid present. I considered that these observations of Sir Alfred Garrod as to the absence of uric acid from the blood of birds were of so great importance, in view of the opinion which I strongly entertain that uric acid in health is only formed in the kidneys, that I thought it desirable to repeat the experiments. I accordingly worked on very large quantities of the blood of the turkey, goose, duck, and fowl. After the most careful examination I have never been able to detect any uric acid in the blood of these birds, and I therefore confirm Sir A. Garrod's observations. I am also able to confirm his observations as to the presence of urea in the blood of birds. I found urea present in the blood of all the birds that I examined—viz., the turkey, goose, duck, and fowl. Dr. John Davy examined the blood of two snakes (*viper communis*) for uric acid, but failed to detect any.

This mass of experimental evidence, which shows that uric acid is never present in the blood of human beings in health, and also that it is never present in the blood of birds and serpents although their urinary excretion is almost entirely composed of a compound of uric acid, conclusively supports the view advanced by Sir Alfred Garrod and held by Dr. Latham, and in a modified sense by Kolisch, that uric acid is normally produced in the kidneys. How is it possible in all these cases that uric acid could be absent from the blood if the view be correct that uric acid is formed in the system generally and is conveyed in the blood to the kidneys, which play, as it were, merely the part of a filter in the removal of the uric acid from the blood? I consider that the evidence brought forward renders such a view impossible.

SEAMEN'S HOSPITAL SOCIETY.—The annual court of the Seamen's Hospital Society was held on Feb. 25th at the Royal United Service Institution, Whitehall, Earl Spencer being in the chair. The report showed that the society had had under its care during the last twelve months 2616 in-patients and 16,906 out-patients, being in the aggregate the largest number ever treated by the society in one year. The year's income was £15,533 and the expenditure £16,315. The Queen had forwarded her annual subscription of 100 guineas as usual, which made a total of 6000 guineas since the beginning of Her Majesty's reign. The adoption of the report was moved by the Japanese Minister and seconded by Admiral Boys.

WESTERN DISPENSARY.—The report presented at the annual meeting of the Western Dispensary, Rochester-row, Westminster, showed that the gratuitous patients were somewhat fewer last year than during the previous year, which was perhaps partly accounted for by the continued demolition of houses occupied by the poorer classes. The provident branch of the dispensary, however, showed a considerable increase; in 1896 it had 4557 members, the number of visits paid was 14,359, and the payments amounted to £630. Dr. Allchin moved the adoption of the report of the Marie Celeste Convalescent Branch.

The Milroy Lectures

ON

QUARANTINE.

Delivered at the Royal College of Physicians of London on March 11th, 16th, and 18th, 1897,

BY WILLIAM COLLINGRIDGE, M.A., LL.M., M.D., D.P.H. CANTAB.,
MEDICAL OFFICER OF HEALTH OF THE PORT OF LONDON.

LECTURE III.[1]

Delivered on March 18th.

MR. PRESIDENT AND GENTLEMEN,—In my last lecture I endeavoured to show that the theory on which the system of modern quarantine was based was untenable, and that in practice it had failed to confer any real protection on those countries which practised it. I have now to deal with the practical objection—namely:—

3. *That an effective quarantine is practically impossible in a commercial country.*—In early days, when trade was relatively of small volume, this was apparent, and the enormous growth of commerce has simply emphasised the fact. The question could only be considered at the present day with reference to the period of incubation, and it would obviously be accepted that any vessel was safe if there had been no case of disease during a period at least equal to that of the possible latency of the disease. Sir John Simon, in his eighth report, says: "For the purpose of the argument we assume that an allowance of ten days will cover the time during which infection can be latent or designedly concealed, which, however, is less than the time on which quarantine Governments insist, and I believe only half the time of an average quarantine in Greece; and if we translate into practical language what this would mean if England had quarantine against the Continent it would be that ten days would be the minimum time in which any person, sick or healthy, could enter England from the Continent—that, for instance, our present ninety minutes between Calais Pier and the Dover railway-station would become an affair of at least ten days, and that no national advantage from quarantine could be promised if this rule were in any case relaxed or evaded."

Again, nearly thirty years later, when our shores were once more threatened with cholera and when various sanitary authorities and other bodies were urging the Government to abandon their traditional attitude and impose a period of detention upon all arrivals from infected countries, Dr. Thorne Thorne, in his Report of 1892-93, thus sums up the absurdity and impracticability of the suggestion: "'Put all ships from infected ports into quarantine' was one demand. Let us apply this to a few only of our ports. Between the end of September, 1892, and January, 1893, there occurred in Calais some seventy attacks of cholera, of which twenty-four terminated fatally. The port of Calais was thus an infected port. Between Sept. 24th and Dec. 14th, 1892, cholera was prevalent in Boulogne, causing thirty deaths. The port of Boulogne was thus an infected port. Now, in the six weeks ending Nov. 12th, 1892, the mean weekly number of passengers arriving at Dover from the port of Calais was 1800, and if a quarantine of five days had been imposed upon arrivals from this infected port the total number of persons who would have had to be detained, housed, fed, and otherwise cared for, either afloat or on shore, by the Dover Sanitary Authority would, apart from the crews of the vessels, have amounted to 10,894, the number under detention at any one time ranging from 1019 to 1723. Dealing with Folkestone in the same way, it appears that during the six weeks ending Nov. 12th, 1892, the total number of passengers arriving from the infected port of Boulogne was 3251, that the mean weekly number of persons who at one time would have had to be detained at Folkestone under a five days' quarantine would have ranged from 272 to 673; and, owing to cholera at other ports, such as Dieppe

[1] Lectures I. and II. appeared in THE LANCET of March 13th and 20th respectively.

Hosted by Google

and Havre, similar measures would have had to be carried out at other English ports, notably at Newhaven and Southampton. Apart, indeed, from an almost complete cessation of traffic between the ports concerned, such as might have been brought about by any real attempt at quarantine restrictions, the result obtained would have been one which could only have brought ridicule upon our sanitary administration." Dr. Thorne Thorne further remarks: "Obviously such a system would break down at its first application, unless exemptions were made which would at once destroy the value of the attempt to impose a quarantine on arrival from any one port, such as were demanded in the case of Hamburg." He points out that "this would be absolutely futile and would merely involve vexatious expense and delay to passengers, who would travel by rail from the port in question and take ship at other places against which there were no restrictions." Indeed, as a matter of fact many persons at that time, fearing detention, did arrive in England from Hamburg, having embarked at Dutch, Belgian, and even French ports.

It is scarcely possible for those not personally interested in shipping to realise how serious a matter quarantine has been for shipowners, not only in the remote past, but even at a very recent date. Firstly in importance would come, without doubt, the loss occasioned by delay and uncertainty of detention, and even in some cases actual prohibition of intercourse with infected ports or ports supposed to be infected. Dr. Bowring, after extended travel and experience of quarantine, says that the "pecuniary loss inflicted by the system may be estimated by millions of pounds sterling in delays, demurrage, loss of interest, deterioration of merchandise, increased expenses, fluctuations of markets, and other calculable elements; but the sacrifice of happiness, the weariness, the wasted time, the annoyance, the sufferings inflicted by quarantine legislation—these admit of no calculations, they exceed all measure." It seems impossible that trade could ever have been carried on under the vexatious and harassing restrictions at one time in force; obviously trade as understood at the present day could not have existed. Thus, so recently as 1827 all vessels bound up the River Thames from ports east of Gibraltar were compelled to run into the Medway and perform quarantine in Stangate Creek. Such a waste of time and money would be utterly impossible at the present day.

Apart from the detention which was an essential part of the system there existed the greatest uncertainty at all times as to the existence of the disease which rendered such detention compulsory; the merest rumour or suspicion of disease was often held sufficient to justify imposition of the most rigorous quarantine, and this must of necessity have been the case. Even at the present time, with all the facilities that now exist of postal and telegraphic arrangements, it is always difficult to obtain accurate information as to the existence and nature of diseases prevailing in foreign countries. The policy of concealment is constantly adopted in order to avoid the actual or imaginary interference with trade which may follow the declaration of the presence of an epidemic, and the officially confirmed facts are obtainable only after the disease has spread to such an extent that its existence can no longer be denied. First cases of cholera are called "sporadic" or the term "cholerine" is used, with the hope that they may not become sufficiently numerous to call for investigation on the part of other countries. This is, indeed, a strong argument against such restrictive measures as interference with the carrying on of trade. It not only leads to concealment, in itself a great danger, but further, on account of the desire to keep the true facts secret, prevents the authorities from taking due measures to prevent the spread of infection. On account of the delay in obtaining accurate information action must be taken by other countries in self defence on mere rumour, otherwise sufficient time would elapse for vessels to reach a country before the port of departure was authoritatively known to be infected. And the same danger arises at the close of an epidemic, it being found necessary to continue restrictive precautions for a certain (or rather an uncertain) period after all danger is officially declared to be at an end. Egypt in 1865 had prepared an elaborate system of quarantine for all pilgrims returning from Mecca, but the disease was not recognised before many vessels had arrived and Alexandria had been infected by their means. "Next, before Alexandria confessed itself infected it had infected Marseilles and France generally. Then before Marseilles confessed itself infected Valencia had received a most disastrous infection from or through it; Odessa before it was recognised as itself having cases of cholera had let infection pass through it, first to start in Podolia an epidemic which diffused widely in South Russia, and secondly to start at Altenburg, in the middle of Germany, an epidemic which diffused widely in Central Europe. Italy received its infection through the quarantine establishment at Ancona, which both infected the town of Ancona by sending infected things to be washed there and also allowed an undiscovered case of cholera to pass on from its lazaret after six days' detention to infect the town of Pisa."[2]

Further instances of the futility of relying upon official reports of infection are given in Mr. Netten Radcliffe's Report on Cholera in Europe in 1873. The first intimation of the presence of cholera in St. Petersburg was received on Sept. 9th, the disease having appeared there on Aug. 9th. Cholera was officially recognised in Havre on Sept. 2nd, the disease having been present there since Aug. 9th, and after a formal contradiction of the presence of the disease on Aug. 29th. The first intimation of cholera in Hamburg was received on Aug. 5th, after inquiry made in this country in consequence of several cases of cholera having been landed at Blackwall from a ship which had sailed from Hamburg on July 26th. Cholera had been present in that port since June 21st. Information was received of cholera in Rotterdam on Oct. 18th, but its existence there was not officially declared by the local authorities till Oct. 27th. Information was received of the presence of cholera in Antwerp on Oct. 25th, and at that date clean bills of health were still being issued to ships leaving the port. Again, in 1892, at Hamburg, the first official intimation of the outbreak of cholera was received on Aug. 23rd, though it was subsequently ascertained that 447 cases had occurred, with 121 deaths, previously to that date, and the first cases from that port had arrived at Grangemouth on the 19th.

A somewhat similar danger still obtains with reference to cargoes such as rags, clothing, &c., considered as capable of conveying infection, and this danger appears to be fatal to the policy recently in vogue in this country of issuing Orders for limited periods prohibiting the importation of such goods unless previously disinfected. The immediate result of such Orders has been to seriously interfere with a special class of traffic for a certain period. Assuming that such materials do carry infection—and the evidence is by no means clear on this point—it must be remembered that although shipped at a certain port they are not necessarily produced or collected within the immediate neighbourhood. Thus rags might be introduced into this country from an infected district without any precautionary measures, because they were shipped from a country not declared infected; or, on the other hand, materials sent from an infected port might have been obtained from a district where no disease had appeared. Again, no Orders were issued until the disease was well established, and therefore these goods might be freely imported from an infected district up to the time of the promulgation of the Order. Further, one effect of such an Order is necessarily to increase the cost of the material owing to the compulsory disinfection. The traffic would, therefore, to a certain extent (varying according to the state of the market and the laws of supply and demand) be arrested, and stocks would be accumulated in the infected countries. As soon as the epidemic was at an end and the prohibitory Order revoked these stocks would be shipped, and thus the very goods collected in the infected country during the prevalence of disease, and detained for a certain time, would be once more freely admitted. If these goods were capable of conveying infection it would be far more reasonable to insist upon their disinfection at all times. If this were a settled principle arrangements would be made whereby they could be disinfected at small cost and the intermittent dislocation of trade avoided.

The impossibility of a strict quarantine in the present day, as well as its failure, are well shown by the history of the attempt to carry it out in the United States in 1892. A vessel coming from Hamburg, carrying immigrants, arrived at New York, having had twenty-two deaths from cholera during the voyage. A minimum quarantine of twenty days was thereupon imposed upon all vessels carrying immigrants. This soon led to a total cessation of the emigrant trade, but in the meantime a large number of persons (some thousands) were

[2] Mr. Simon: Report to Privy Council and Local Government Board, 1875.

Hosted by Google

detained under conditions which were described in the daily press as "inhuman and revolting." The quarantine was only partly carried out, as it was soon found to be impracticable, while at the same time unhappily the disease found its way into the city, where sixteen persons were attacked, with twelve deaths.

As instances of the imposition of quarantine without due cause, Milroy quotes the case of vessels from Great Britain being quarantined at Messina in consequence of a report in a French newspaper of a case of typhus having occurred at Glasgow, while a cargo of cotton from New Orleans which had been landed and re-shipped at Liverpool had been declared infected after a subsequent voyage of more than fourteen days' duration. In 1858 a P. and O. steamer in Alexandria landed some passengers at Gibraltar, and before leaving it was necessary to obtain a bill of health. This was sent on board in a tarred box, fastened. The captain, not aware of any risk, opened the box, and in consequence on arrival at Malta had to undergo a quarantine for ten days for communicating with an infected port. At Alexandria a vessel arrived with pilgrims from Tunis; one died on the voyage, and after some controversy it was decided to consider the disease as plague. The pilgrims were landed in a lazaret, where another died. Again there was some conflict as to the nature of the disease, but the majority of the authorities considered it as plague One of the medical men had touched the corpse, and had gone home without undergoing the prescribed purification. This became known to the foreign consuls, who communicated the facts to their respective Governments, with the result that Alexandria was declared to be infected with plague. In the report of the proceedings of the Quarantine Committee of the Social Science Association it was shown that all arrivals from Egypt and Turkey, without exception, had been subjected at nearly every port in the Mediterranean to a more or less lengthy and strict quarantine, although it was well known that no plague had been seen in those countries for twenty years. Again, arrivals from the West Indies, Gulf of Mexico, and the West Coast of Africa are always quarantined in Spain and Portugal, whether or no yellow fever exists in those countries.

The records of quarantine in our own country reveal some extraordinary facts. In a Parliamentary return prepared in 1853 it is stated that in 1848 sixteen vessels were detained for periods varying from three to six days on arrival from Hamburg, although there had been no sickness on board during the voyage, on arrival, or while in quarantine. In 1754 the sloop *Fowey*, from Algiers, arrived at Gibraltar with a clean bill of health, having had no sickness on board during the voyage. Here she rode out six days' quarantine and left for Portland, and arrived after a month's voyage, during which all were well on board. The captain and crew all went on shore, and some persons from Weymouth went on board. She then sailed to Guernsey and received free pratique, but after twenty-four hours all the crew were ordered on board and the vessel was directed to perform quarantine at the Motherbank. There she remained with all her crew in perfect health for four months, when, without any reason being assigned, she was taken out to sea by one of Her Majesty's cruisers and sunk off Start Point. In 1731 two vessels from Cyprus, having cotton and other goods on board, were burned by order of the Privy Council at an expense of £29,935, although there had been no sickness on board. Cases have constantly occurred when a healthy vessel has been quarantined because she has come from an infected, and in some cases even from a non-infected, port, although the port of arrival was itself infected at the time. In 1838 the *Firefly*, from Beyrout, arrived at Alexandria with a bill of health stating that there had been no plague at the former place for a period of thirty-six days. She was nevertheless compelled to undergo a quarantine of twenty-two days, although the disease was prevailing at Alexandria at the time. In 1801 two vessels from Mogador, with cargoes of hides, suspected of carrying the infection of plague, were sunk at the Nore at a cost of £15,000, although all on board were known to be in good health. Indeed, so recently as 1846 Dr. A. White, Inspector of Military Hospitals and Superintendent of Plague District in Corfu, in "A Treatise on Plague, with Hints on Quarantine," says: "I am aware that the expurgation of a plague ship with a cargo of goods is a very difficult, tedious, and expensive operation, as well as one not free from danger. I am, nevertheless, of an opinion that, generally speaking, it will be the best, and perhaps the cheapest way in the end, to destroy ship and cargo at once and to place the people under strict quarantine until their state of health is proved to be free from all infection."

To keep up quarantine, with all its elaborate machinery of medical officers, lazarets, quarantine guards, &c., involved enormous expense. Even in this country, where no proper lazarets existed and where the system in its entirety was never thoroughly carried out, the cost was considerable. As I previously mentioned, the charges to the shipowners were very heavy, frequently amounting to 35 per cent. of the value of the cargo; while to the country during the years 1801–1823 inclusive the cost amounted to £641,000 (London £158,000 and the outports £483,000), or an average of £18,000 a year. In 1734 the total expenses were £17,849; in 1829, £23,000; and 1826, £26,000. During the years 1840–1850 they averaged £10,800 a year. All this vast machinery of defence had to be maintained in working order if it were to be suddenly brought into use. Lazarets, fully equipped with all the necessary officers, attendants, and guards, could not be provided suddenly, but were of necessity kept in readiness for an emergency which might rarely occur and only at long intervals of time. Hence the expense was continuous, though the actual need for the use was but occasional. For although all vessels from certain countries were detained, this was done with the object of arresting disease arising from those which were actually unhealthy, the quarantine being a probation to establish the fact of infection or otherwise. According to returns between the year 1720 and 1843 (123 years) only twenty-five vessels with plague actually on board arrived at all the ports of France and Italy—ten of these at Marseilles, five at Venice, nine at Leghorn, and one at Genoa. Those at Marseilles were in the years 1741, 1760, 1784, 1785, 1786 (two), 1796, 1819, 1825, and 1837. The total number of cases, including all doubtful ones, at this latter port was only thirty-two, with eighteen deaths. For these few cases the two countries were put to an enormous outlay, and the vessels arriving there subjected to serious and vexatious delay with its attendant heavy expense.

The most serious objection to quarantine, however, apart from its futility, is the actual danger to health which it involves from the detention of a large number of vessels under conditions in most cases insanitary, and in all more or less unfavourable to the preservation of health on board an infected vessel or in confined lazarets within range of the infection if such exist. For either there is no necessity for their quarantine or they are unreasonably kept more or less exposed to the risk of infection, which is unjustifiable. The case of H.M.S. *Eclair*, in 1845, affords an unfortunate example of the danger to the crew of an infected vessel from the imposition of quarantine. This vessel, on arrival, was first sent to the Motherbank, but on account of the difficulty of communication during bad weather she was sent to Stangate Creek, admittedly one of the most bleak and sickly places on the whole coast of Kent, and this in spite of the strongly worded advice of Sir John Richardson that the sick should be landed and conveyed to Haslar Hospital. In consequence of this action they were confined to the foul atmosphere of the vessel, with the result that over 200 of the crew who had hitherto escaped fell sick and died. This case attracted so much attention that the term of quarantine was considerably shortened. Dr. Gregson, in writing of quarantines, says: "From their oppressive and partial operations they have, instead of diminishing, propagated the disease. Hundreds have been sacrificed by being torn from their homes and thrust into crowded, overcharged, and tainted lazarettes. To sum up, in countries where quarantine has been strictly enforced disease has been imported; in others where quarantine has been loosely carried out disease, though it has appeared before, has been absent for long periods; while in some countries where there was no quarantine the disease has occasionally presented itself."

But, unfortunately, the maintenance of the system extended its pernicious influence much further. It engendered in the minds of the inhabitants of those countries which maintained it a false feeling of confidence for which there was no foundation, and which led them, believing themselves sufficiently protected against the importation of disease, to neglect those measures of sanitation which alone are of any avail against the spread of infection. It is a matter of history that in those countries where quarantine has been most rigorously carried out there common-sense precautions against disease have been most disregarded and the general principles of national hygiene

Hosted by Google

most neglected. The reasons are not far to seek. They feel they have done what is necessary to protect themselves, and cannot therefore realise the value of sanitary measures of rational sanitation which are so essential for the health of the country. Dr. Farr, in his Report on the Cholera of 1866, says: "Quarantine absorbs all the attention of the authorities and serves as an excuse for the neglect of extensive hygienic measures of water-supply and purification." Dr. Thorne Thorne, C.B., in his presidential address to the Epidemiological Society in 1887, says: "The beneficial results which have ensued in regard to the saving of life from cholera have in no small measure been due to the fortunate abandonment by this country of all endeavours to keep cholera away from her shores by a system of quarantine. I recently brought under the notice of the Epidemiological Society the attitude that we have finally adopted in this matter. It is one of distinct opposition to the entanglement of this country by means of a delusive system offered anew, under the plea that another reduction should be effected in the duration of a detention which even under its most stringent forms had been mainly characterised by ever repeated failure. The system of quarantine has again and again shown itself powerless for good, and being so its vexatious and inhuman characteristics stand out the more prominently. Above all, it has a blighting effect upon sanitary progress. So long as Governments tell their peoples that a line shall be drawn around them across which disease shall not pass, so long will those peoples be reluctant to spend their money on the promotion of true measures of prevention. The quarantining countries are essentially those which cholera invades. Taken as a group they are those where the sanitary progress is at its lowest ebb; and with the experience we have before us I would, in conclusion, ask, Is it likely that this nation will sacrifice her well-tried system of prevention for a restriction of five days' quarantine?"

4. *Sanitation and a rational system of medical inspection have proved more efficacious and less burdensome.*—The large sums expended by this country in carrying out works of sewerage and water-supply and in public health administration have not been wasted. If quarantine had succeeded in preventing the entrance of those diseases against which it was directed, its beneficial results would have stopped there; whereas the expenditure on sanitary works has not only enabled us to cope with these same diseases in a more thorough and rational way, but has been instrumental at the same time in greatly improving the general state of health of the community. The public mind has been educated to the necessity for sanitary improvement and the important part which it must play in protecting the people from the ravages of disease. All attempts to conceal or minimise outbreaks of infectious disease have been avoided, and the means adopted for coping with them are as widely made known as possible. An attempt is made, and to a great extent happily successful, to intercept by means of medical inspection at the ports all cases of imported disease. Where this attempt fails reliance is placed upon the sanitary condition of the district to which the infection may be conveyed. If the sanitary condition of such district be good, its system of drainage and sewerage satisfactory, and its water-supply pure and abundant, then experience confirms the theory that there is but little to fear from a spread of the disease, and that it may reasonably be expected to be confined within narrow limits. At the present day it is not necessary to enlarge upon the importance of measures of sanitation, this being fully realised, though still but imperfectly carried out. As far back as 1821 Dr. Hancock, in his work, "Researches into the Laws and Phenomena of Pestilence," thus alluded to the subject:—"It must surely be manifest that foreign contagion, now actually considered the substantial germ without which the most fearful combination of indigenous causes—famine, filth, misery, corrupt food, vitiated air, and sickly seasons—can never produce a pestilence, dwindles in national importance almost to a shadow on comparison. And it can scarcely be doubted that the attempt to defend ourselves by quarantine regulations while such causes existed would be like binding in chains a ferocious animal at a distance when another ten times more fierce was fondled at our doors and suffered to roam about at pleasure." The Report of the General Board of Health in 1849, quoting Russel of Aleppo, who lived there while the plague raged for three years, says: "The city of Aleppo, though in unrestricted and constant communication with Egypt and other ports of the Turkish Empire where the plague appeared annually, used to be affected on an average only once in eighteen years." The unknown influence which they called an epidemic atmosphere was also reckoned by the ancients to be an inevitable forerunner or concomitant of spreading sickness. "In their judgment half the cause, at least one blade of the destroying shears, is forged at home, and without it the other cannot do the work of fate."

Unfortunately in most countries where quarantine is practised the restrictions have been so severe that the interests of commerce have trained for their own purpose a band of mercenary officials and an elaborate system of bribery and corruption. This has been encouraged by the fact that in several cases the formality has been found utterly impossible, as for instance on the visit of a sovereign or ambassador of a foreign Power. In such instances the detention was perforce dispensed with, and the rule once broken through it is not difficult to see how in other cases the desire to avoid delay and expense led to the purchase, direct or indirect, of a like privilege, until in some countries the system was eventually practically reduced to one of blackmail. Those who paid best received the most attention, and the supposed protection by probation became an absolute fiction. In the case of one European State the system had become so oppressive and withal so corrupt that it was fitly described as "a system of tyranny, tempered by 'baksheesh.'" Dr. Brown, of the United States Army—after showing that yellow fever does not originate in the States, but is brought by vessels from foreign ports, and giving the case of Natchez, which was not visited by yellow fever before steamboats began running on the Mississippi in 1819, but after that year was attacked whenever the disease prevailed in New Orleans, and never at any other time; also that of Vidalia, where yellow fever never appeared before 1843, when steamboats first called there; and again that of Sabine and Matagorda, which had coast-wise trade, and were never attacked until the severity of the blockade at Galveston and the possession of New Orleans by the Northern forces made them convenient for blockade runners—says: "New York established a rigid quarantine in 1882, and although it has been brought every year to the port it has only twice appeared within the quarantine lines, in each being plainly traced to evasion of the quarantine law." I should here point out that this example of the effect of quarantine in arresting yellow fever is in itself no argument in favour of quarantine simply, inasmuch as the American system involves the complete disinfection of the vessel itself, a measure which is indispensable in dealing with this disease. He further states that Philadelphia was exempt for fifty years, except in 1853, when the barque *Mandarin* was improperly allowed to pass. These were simply instances, then, of the impossibility of preserving an absolutely efficient system. Dr. Choppin of Louisiana[3] says: "No conditional quarantine can ever be made effective, because of the laxity with which laws are, unfortunately, executed in this country; and, secondly, because of the cupidity of commercial interests at stake, which will always move heaven and earth to evade successfully all quarantine laws and regulations." The latter statement will apply with equal force to any other country. While it is not right to condemn a system because of the abuses which have crept in, still these have been so constantly associated with quarantine that they have with a certain amount of reason at last come to be considered as an inseparable part of it. Before the Select Committee of the House of Commons which sat in 1824 evidence was given by merchants to the effect that foul bills of health were deliberately and without any justification issued so that a market could be made in Holland while British vessels would be delayed here, the issue of such bills being arranged by the Greek merchants at such times as the state of the markets rendered it desirable in their interests to forestall British vessels. Again, for political purposes quarantine had been made use of with effective results. At one time during an insurrection in Sicily it was stated on good authority that a quarantine of eighty days was imposed upon certain vessels bringing help to the rebels, during which interval the rising was successfully dealt with.

It is evident that some reasonable system of safeguarding a country from the importation of diseases is not only desirable, but even essential to its welfare; and that, apart from its fallacies, its dangers, and actual cruelties, quarantine at the present day is impossible—i.e., that no country can submit to a system which, while affording no real protection, would by its paralysis of trade lead to poverty and

[3] Medical Times and Gazette, 1873, vol. i.

Hosted by Google

misery, which would in turn produce conditions favourable to diseases tenfold more terrible than those it was assumed to be a protection against. The true defence against epidemics is a healthy condition of the people, fostered by all the care and attention that can be given to it by our legislators and sanitary authorities, and it is upon this that England in the main relies. The Public Health Act, in addition to ordinary sanitary powers, provides for the isolation and treatment of infectious sick and the disinfection of houses and clothing; while the Notification Act compels the fact of such disease being reported to the sanitary authority whose duty it is to put these preventive provisions in force. As the ordinary zymotic diseases—such as diphtheria, enteric, typhus, and scarlet fevers, and small-pox—are always in our midst to a greater or less extent, and as the existing powers of sanitary authorities are deemed ample to cope with them here, it is clearly logical to believe that they would be sufficient to combat any cases of the same disease brought by vessels to our shores. But this is not at present the view taken by many authorities in this country. Because such cases happen to be on board a vessel, instead of arising within our own limits, it is suggested that such ship should be submitted to a course of detention and isolation which in the case of a house has scarcely ever been thought of. The compulsory notification, removal to hospital, and subsequent disinfection are ample to ensure safety; and there is no more justification for the detention of healthy persons on board a ship on which a case of small-pox has occurred than there is for the enforced isolation of the inmates of a house in which the same disease has appeared. Yet in the one instance the question has never been discussed, at least in this country, while the other has had many strong advocates.

With reference to those diseases which do not ordinarily, or but rarely, exist in this country, more stringent measures may justifiably be employed, though these must be of such a nature as not to interfere unnecessarily with the interests of intercourse. The term "medical inspection" as employed in this country means that in each port a medical officer of health is engaged, whose duty it is to visit each ship on which any case of cholera, yellow fever, or plague is suspected to exist, the suspicion or fact to be derived from the master of the vessel (except when a surgeon is carried) or a custom-house officer. This is surely a misuse of the term. If medical inspection means anything, it implies that a medical officer visits every vessel from "foreign" ports and examines every case of sickness whatever its nature, and every person on board if the vessel has arrived from a port which is known to be infected. This is a system which, while in no way interfering with trade, affords the utmost protection which is possible or even desirable. The isolation of the sick and the disinfection of the vessel follow exactly the same lines as those employed on shore, varying only as the nature of the infection requires this or that treatment for its destruction. This is not advocating any novel experiment or the use of untried measures. During the last twenty-five years there has been ample experience of what may fairly be called the English system, and its value has been sufficiently demonstrated to justify future reliance upon it. To deal only with the last outbreak of cholera on the Continent in 1892-93, during the months of August, September, and October, 1892, while the cholera was raging in the city of Hamburg free and unrestricted intercourse was carried on between that port and this country. Although no fewer than thirty-five cases of cholera were introduced into our ports during that period (eleven of which proved fatal), in no single instance was there any spread of the disease beyond the persons arriving infected. These thirty-five cases were brought by twenty vessels, from four different ports, fourteen coming from Hamburg. All but seven of the thirty-five cases were arrested on arrival by the sanitary authorities of the nine ports at which they arrived, while in three instances only was the disease not recognised until the patients had reached their destination inland. These seven patients were isolated in hospital, and the usual precautions taken.

Realising the fact that the trade interests, nay the very existence, of the Empire would be imperilled by any return to the absolute system which has failed whenever tried, the Government will still depend for safety upon a rational system of medical inspection at the ports as the first line of defence, and upon the maintenance at an increasingly high standard of sanitation throughout the length and breadth of the land for the second line of defence in the event of the first line being broken through. At the last International Conference many of the European Powers were inclined to follow the same lines, but unhappily this has not been a lasting Convention. While I write these lines a new Conference of the European States is meeting to discuss the measures to be taken to prevent the importation of plague, and it is generally believed, and not without some solid foundation for the belief, that some of those countries which have previously agreed to abandon quarantine will, under the influence of what is little else than panic, again revert to a system which has deluded them in the past, and will doubtless again fail them in the future. England is likely to be the only country there represented which will be found willing to continue her present system without modification or alteration. It is somewhat difficult to ascertain definitely the varying views of foreign countries on the question, or to estimate fully the effect upon their action of the Dresden Convention. This Convention was signed by Great Britain, Germany, Austria-Hungary, Belgium, France, Italy, Russia, Switzerland, Luxemburg, Montenegro, and the Netherlands. Some idea of the extent to which this Convention influences these and other Powers in dealing with plague may be gathered from the following notifications made officially through their Governments. On Oct. 13th, 1896, a quarantine of ten days was imposed by Turkey on all arrivals from Bombay. On the same date the Spanish Government notified the imposition of quarantine on all vessels which had left Bombay after Sept. 18th; Calcutta was added on Oct. 27th. On Oct. 29th the quarantine board at Cairo issued an order compelling disinfection of all vessels bound from Bombay to Suakim. On Nov. 3rd twenty-one days' quarantine from the date of starting was imposed upon all vessels arriving at Bussora or other Turkish ports from Bombay. On Nov. 13th Malta (a British possession) imposed a quarantine of twenty-one days upon all vessels on which cases of plague or suspected plague had occurred, and on the 19th another order was issued requiring all vessels from Bombay to proceed to the quarantine harbour and there land all luggage, clothing, and cargo for disinfection; while on Feb. 1st a quarantine of twenty-one days, with landing and disinfection, was ordered. On Dec. 4th Cyprus imposed a quarantine of ten days at Larnaca on all arrivals from Bombay. On Jan. 5th, 1897, Natal imposed a quarantine of twelve days after disinfection on arrivals from Bombay. On Jan. 5th Constantinople notified ten days' quarantine on arrivals from Kurrachee and rigorous disinfection. On Jan. 29th the sanitary board at Tangiers decided to refuse admission to arrivals from India with foul bills of health. On Feb. 1st Gibraltar announced that vessels from India would not be allowed pratique. On the same day Lisbon notified that all vessels from India would be subjected to rigorous disinfection, and passengers and crews placed in strict quarantine. Tunis refuses communication with all vessels from India for coaling or otherwise. On Feb. 4th Holland declared ten days' quarantine on arrivals from Bombay and Kurrachee; while on the same date all arrivals from India were refused admittance into Morocco. On Feb. 8th the port of Constanza was closed by Roumania to all vessels from Indian ports. On Feb. 12th the French Government decreed that passengers arriving from infected ports could only enter at Pauillac, St. Nazaire, Havre, or Dunkerque, and that before landing they should be subjected to an observation of eight days at Pauillac and St. Nazaire, and four days at the other ports, and that all their baggage should be disinfected.[4]

The sanitary condition of our vessels must always be a most important question, though unfortunately it has not hitherto received the attention that it deserves from a public health point of view. Ships travelling to all parts of the globe are obviously exposed to the danger of infection from the diseases of any port in which they may happen to lie. Sailors when in port, as a rule, frequent the

[4] The International Conference has decided that persons arriving on board ship with plague are to be immediately landed and isolated; the rest of those on board to be subjected to a surveillance not exceeding ten days, counting from the development of the last case; passengers' personal effects, luggage generally, and goods or cargo to be disinfected; the bilge water shall be removed before the general disinfection of the ship. Suspected vessels shall be subjected to a simple medical visit, but the passengers' personal effects and those of the crew will have in every case to be disinfected. Special measures will be taken by each Government for the ships conveying emigrants or found to be in bad hygienic condition. Ships declining to undergo such measures will have to land their passengers and goods. The former as well as the latter will have to undergo the regulation measures, after which the ships may continue their voyage.—THE LANCET, March 13th, 1897, p. 763.

Hosted by Google

lower quarters of the town, and are therefore at each port exposed to a fresh risk of infection. Thus their chance of becoming infected is greater and more varied than that of the corresponding class on shore. In the case of merchant ships the majority of seamen are during the voyage beyond the reach of medical aid, and therefore, for the sake of humanity alone, their surroundings should be made as hygienic as possible under the circumstances. The calling of the seaman would appear at the first sight to be a healthy one, as he spends a large part of his time in the open air removed from the close and confined atmosphere of towns, and undoubtedly he has many advantages; on the other hand, he suffers from frequent exposure to wet and cold, and hence is unduly subject to various forms of rheumatism. From the limited air space and the fact that, owing to the system of watches, forecastles are always occupied, and therefore never thoroughly ventilated, all forms of lung disease are exceedingly common. These causes and the violent exertions that sailors are called upon at times suddenly to undergo fully account for their high mortality and sickness-rate. In the Royal Navy the death-rate in 1892 was 5 58 per 1000, while in 1886 in the merchant navy for sailing ships the rate was 21 and for steamships 9·6. Although during the last twenty-five years great improvements have taken place and much more attention has been paid to naval hygiene, it is still a fact that so far as sanitation is concerned the sailor is a long way behind his fellow worker on land. He is entirely dependent for food on the vessel in which he lives, and provided a scale which is given him on engagement is adhered to there is no law to require that such scale should be either reasonable or sufficient. As a matter of fact the majority of diet scales in use in our merchant service are not sufficiently nutritious or varied for men doing hard work, nor, indeed, are they by any means the best that can be provided for the money that is expended upon them. Better dietaries and better cooking are urgently needed. A larger amount of cubic space than that compelled by law (viz., 72 cubic feet per head) is absolutely required, and what, perhaps, is more necessary some guarantee that such space should be properly utilised and fitted for the purpose which it is intended to serve. At the present time there is a grave anomaly with reference to this question. Before a house can be erected a plan showing the drainage and sanitary arrangements must be submitted to the sanitary authority, with whom rests the responsibility of approving or otherwise; while in the case of a vessel no such provision obtains. As a general rule in designing a vessel a certain space is set aside for the crew, and when she is completed this space is utilised in the best way possible by an artisan without reference to a sanitary authority and without any control, except that exercised by the Board of Trade under the limited (from a sanitary point of view) powers of the Merchant Shipping Act. The arrangement and fitting of crews' quarters under the supervision of a sanitary authority, advised by an expert, would be a benefit both to owners and seamen, and would be of great value in preserving the health of those on board. The constant and close supervision of vessels while lying in the port, and the prompt abatement of all nuisances and conditions likely to prove injurious to health, is essential. Milroy, in his "Quarantine as it Ought to Be," specially lays down that vessels in a filthy and unwholesome state from foul bilges or otherwise should not be allowed (sickness or no) to enter a crowded port, or to lie alongside a wharf, or to land cargo till they have been cleaned out and ventilated. A foul ship is itself more to be dreaded than anything she may have on board. The United States Government has always laid great stress upon the sanitary condition of vessels leaving foreign ports for their shores. They require a bill of health with actual information as to the health of the vessel on leaving. Rohe quotes as an illustration of the value of this system, from a report by the medical officer of the Marine Hospital at Naples, that eight vessels left that port during the year 1893 when cholera was epidemic, these vessels being under similar conditions as to water-supply and food and carrying passengers of similar class and origin. In four leaving without any sanitary conditions there were 50, 90, 84, and 230 deaths respectively. In the four leaving for the United States on which sanitary precautions were carried out no sickness occurred.

From a public health point of view it is thus clear that the sanitary condition of our mercantile marine is a matter of the utmost importance, not only to ship-owners and masters, but to every inhabitant of this country. Upon it we have to rely as a definite part of our system of defence against the importation of epidemic disease, a part which is at least as essential as medical inspection or the maintenance of the sanitary condition of our population on shore. If this be once realised it will probably lead to increased attention being paid to the health and surroundings of our seamen, which is urgently needed if Great Britain is to continue to occupy her present proud position among the great commercial countries of the world.

ILLUSTRATIVE CASES OF APHASIA.

BY BYROM BRAMWELL, M.D., F.R.C.P. EDIN., F.R.S. EDIN.,

ASSISTANT PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, SCHOOL OF MEDICINE, EDINBURGH, ETC.

(Continued from p. 801.)

CASE 2. *Complete word-blindness; right-sided homonymous lateral hemianopsia; no agraphia, but inability to read own writing; optical aphasia; temporary mind blindness; the ability to spell correctly completely retained.*—The next case, which came under my notice several years ago, is an excellent example of word-blindness without agraphia and of temporary mind-blindness. It was closely observed for four years and presents many points of interest and importance. Although there was no post-mortem examination, there can, I think, be little doubt that the lesion was either a hæmorrhage or softening situated in the back part of the left hemisphere, on what I may term the peripheral side of the visual speech centre (angular gyrus), that is to say, between the half-vision centre and the angular gyrus. The fact that the power of writing and perfect ability to spell were retained seems to show conclusively that the visual speech centre itself (the angular gyrus) was not implicated and destroyed by the lesion; while the complete word-blindness and the very remarkable condition of mind-blindness (which persisted for many months) probably show that the lesion was situated above (on the higher cerebral side, so to speak) of the half-vision centre. Occlusion of the *left posterior cerebral* artery, with softening of the left half-vision centre, will produce (as in the case to which I have already referred[1]) right-sided homonymous lateral hemianopsia, but does not produce word-blindness, and it is doubtful if a purely destructive lesion in this situation will produce mind-blindness, though an irritative lesion involving the half-vision centre might perhaps do so. For the production of word-blindness the lesion must interrupt or destroy the fibres which pass from both half-vision centres to the left angular gyrus (visual speech centre), or must involve the visual speech centre itself. In the latter case—i.e., when the visual speech centre itself is destroyed—there is always, according to Déjerine, agraphia as well as word-blindness. In this case there was no agraphia; the patient could write quite well, but was unable to read a word of what she had written. In short, the case was an example of cortical or, as Déjerine terms it, pure or isolated word-blindness. The hemianopsia, which was absolute from the date of the lesion up to the time of the patient's death, was no doubt due to destruction of the optic radiations of Gratiolet in the occipital lobe. The mind-blindness was probably an irritative phenomenon, due to the irritation produced around the softening, rather than a destructive or paralytic symptom. The date at which it occurred and the complete way in which it cleared up and passed off are, I think, in favour of this view. But I admit there may well be difference of opinion on this point, for the disappearance of this symptom (mind-blindness) might, if it were a paralytic symptom due to the destruction produced by the lesion, be explained by a process of compensation being established. I am, however, disposed to favour the irritative rather than the paralytic theory, and to think that irritation passing from the back part of the left hemisphere

[1] See THE LANCET, March 20th, 1897, p. 796; and Atlas of Clinical Medicine, vol. ii., p. 40.

Hosted by Google

along fibres passing from the visual centres[2] in both hemispheres to associated cortical centres is the more likely explanation of the mind-blindness and mental alterations which were present in this case. While this condition of mind-blindness was at its height the patient was unable to recognise her surroundings, and she could not recognise by the sense of sight her own daughter, the nurse who attended on her, &c., though she was able to recognise them by the aid of other senses—e.g., the sense of hearing. But, further, the patient did not recognise her own identity—she thought she was a boy, a servant, &c. It is interesting, therefore, to note that a state of mental derangement which to the patient's friends appeared to be a condition of insanity was the result of a purely local brain lesion—i.e., hæmorrhage or softening. Such a condition of mental derangement seems to me to favour the irritative rather than the paralytic theory. In addition to the mind-blindness a condition of optical aphasia (*l'aphasie optique*, as the French writers term it) was present. The patient could not name objects which were shown to her. Another point of interest is the fact that although the patient was completely word-blind—unable to read the simplest words or letters—her ability to spell was so perfectly preserved that the members of her family were in the habit of referring to her on any doubtful point of spelling. In the observation of future cases of word-blindness the patient's ability to spell should, I think, be carefully tested. No doubt in most persons both the auditory word-centre and the visual word-centre are brought into action in the process of spelling, though in most persons the action of the auditory speech centre is in all probability by far the more important of the two. Whether some persons are able to spell by the aid of the visual speech centre alone is one of the disputed points connected with the subject of aphasia. According to Déjerine, the action of the three great speech centres (the auditory speech centre, the visual speech centre, and the motor vocal speech centre)—he does not admit the existence of a separate and independent writing speech centre—which comprise what he terms the "zone of language" are mutually dependent; derangement of one necessarily, he thinks, entails derangement of the others. In this he is opposed to the teaching of the late Professor Charcot and his pupils. The subject is exhaustively discussed by Dr. Charles Mirallié in the important work which he has recently published.[3]

It is probable, I think, that in most persons destruction of the visual speech centre will interfere in some degree (and probably in some persons in a very marked degree) with the power of spelling correctly. If this supposition be correct, it is reasonable to conclude that in most cases of word-blindness such as this, in which the power of spelling is perfectly retained, the visual speech centre (the angular gyrus) is not the seat of the lesion. And, *vice versâ*, that in most cases of word-blindness in which the angular gyrus is destroyed (i.e., is the seat of the lesion) the power of spelling is more or less profoundly deranged. Now, if this supposition be correct, it is obvious that in cases of word-blindness the patient's ability to spell correctly or the reverse is an important clinical means of differentiating the exact seat of the lesion, whether (*a*) it involves the visual speech centre, or (*b*) the tracts proceeding to the visual speech centre from both half-vision centres. And still more, of course, in cases of word-deafness, whether the lesion involves (*a*) the auditory speech centre, or (*b*) the tracts proceeding to the auditory speech centre, since the action of the auditory speech centre is for the purpose of spelling more important than the action of the visual speech centre.

From the report of the case it will be seen that a very slight amount of paraphasia was present. This is interesting, for Déjerine states that in cases of pure word-blindness (such as this case appears to be) there is no disturbance of the motor vocal speech centre—no paraphasia. Another point which should be noted is the decided condition of incoördination which was present in the movements of the right hand. I have noted the same symptom in several other cases of word-blindness with hemianopsia in which there was no paralysis (see Case 1). The notes of the case are as follows. The patient, who up to the time of her illness was in good health, was seized four days before I saw her with severe pain in the top of the head; it lasted for about an hour. After it had passed off her relatives noticed that she was unable to express herself correctly, that she used the wrong words, &c. Next morning the patient was in a dull, apathetic condition, but she talked quite sensibly and well, making no mistakes and using the words correctly; the pupils were rather sluggish, the tongue was furred, the intestinal evacuation was very offensive, and the pulse and temperature were normal. As there seemed to be no evidence of a localised cerebral lesion, the attack was attributed to biliousness. At the time of my first examination I found the patient in bed. The temperature and pulse were normal. The tongue was slightly furred. The heart sounds were feeble, but there was no valvular disease. The liver was of normal size. The urine contained neither albumin nor sugar. The patient stated that she had no giddiness, no sickness, and no headache. There was no paralysis; the grasping power of the right hand was fully equal to that of the left. There was no disturbance of tactile sensibility. The movements of the right hand appeared to be somewhat incoördinate; the patient's daughter stated that she fumbled with her right hand and that she had difficulty in taking hold of objects (her teacup, for example) when they were placed on her right side. The mental condition was dull and apathetic, but there was no obvious derangement either of the auditory speech centre or of the motor vocal speech centre. The patient seemed to understand everything which was said to her and answered every question which I put to her quite intelligently and correctly. There was absolutely no defect in articulation, and there was, so far as I could detect, no paraphasia.[4] Her relatives stated that since the attack her memory was decidedly impaired. It will be remarked that up to this point of the examination no aphasic defect had been discovered; in fact, with the exception of some mental dulness and some incoördination in the right hand, no definite symptoms of disease, nothing indicative of the well-marked localised brain lesion which was present, had been detected. It was only when the fields of vision and the patient's power of reading were examined that the true nature of the case became apparent. The case shows the importance of examining, as a matter of routine, the fields of vision and the patient's power of reading in all cases of obscure cerebral disturbance. The pupils were equal and moderately dilated; they contracted rather sluggishly to light. The patient complained that her sight was somewhat dim. On ophthalmoscopic examination the fundi were found to be normal. On testing the fields of vision right-sided homonymous lateral hemianopsia was found to be present (see Fig. 5). On testing the patient's power of reading it was found that she was unable to read a single letter or word, but she could sign her name and write words and sentences, though somewhat imperfectly. She was, however, absolutely unable to read a single word which she had written. She also had difficulty in naming objects—for example, she could not name either a tuning-fork or a knife. At this stage of the examination she broke down and began to cry, apparently because she was distressed that she could not name the objects that were shown to her. Her daughter said that she was not naturally emotional, but that she had broken down several times in the same way during her present illness.

Subsequent progress of the case.—When I next saw the patient, a week later, the general condition was improved: the tongue was cleaner, the appetite was good, the bowels were acting regularly without medicine; the pulse was of normal frequency, and the temperature 98·6° F. There was no headache, no vomiting, and no giddiness. The patient was sleeping well. The pupils were equal and of medium size; they contracted actively to the stimulus of light, and the contraction seemed as active when the ray of light was thrown on the left (non-seeing) half as on the right (seeing) half of the retina. The right-sided homonymous lateral hemianopsia was still present. The patient could understand everything that was said to her, and answered every question which was put to her correctly and in appropriate language. Her friends said that her memory was still much impaired. She herself said that she felt "in a fog" and that "everything is a blank." She was absolutely unable to read any word, letter, or figure. She could not name a knife when it was shown to her. She could not name her own fingers when she was

[2] I do not say merely the half-vision centres in the tips of the occipital lobes, but the adjacent areas of the cortex in which the primary visual impressions received by the half-vision centres are re-represented.

[3] De l'Aphasie Sensorielle.

[4] From the subsequent reports it will be seen that a slight degree of paraphasia was occasionally present.

Hosted by Google

asked to do so. She seemed quite unable to appreciate her surroundings. Her friends stated that she did not know them and did not appear to know where she was. She signed her name when asked to do so and also wrote the numbers 2 and 8 correctly when asked to do so, but after having written her name and the figures 2 and 8 she was unable to read them. Her friends stated that she still fumbled with her right hand (had difficulty in raising a cup to her mouth with the right hand, &c.), but there was no obvious paralysis. The grasping power of the right hand was quite as good as that of the left. There was no anæsthesia in the right hand to objective tests, but the patient evidently felt that it was different in some way or other from the left. During my visit she frequently looked at the right hand, turned it about, and asked me more than once if I did not see a difference in it. Her friends stated that she would persist in saying that it was different from the left, that she was not sure that it was her own hand, that she thought it did not belong to her, &c. At this visit the patient was a little emotional both at the beginning and end of the examination, but she did not break down in the way she did at my first visit.

Condition two months after the onset of the attack. — During the last month the patient's condition had varied considerably from day to day. At times she had been very much depressed, at others bright and lively. Her appetite and general health had been good. As a rule she had slept well, but some nights she had been restless, others she had cried a good deal and been very much depressed. She was still quite unable to read. She was greatly distressed at this, and her friends said that her one desire was that she might regain the power of reading. She had been more intelligent and more sensible, but the mind-blindness still continued. She did not realise that she was in her own room or in her own house; she did not recognise her daughter who had for years been her constant companion, and who had nursed her during the whole illness. She thought the nurse was a boy; she thought she herself was a boy, a servant, &c. On one occasion she got up in the middle of the night, went out of her bedroom and wandered about the passage. When she was taken back to her bedroom (through another door) she thought she had been on a journey; she said she had gone away in the night and had come back in a boat. On another occasion, after a bad night, she said that she had been travelling—that she had been to India, to France, &c. She thought the nurse was a boy; said he was "an active little chap." On another occasion she thought her medical attendant was a visitor; she said: "He is a very big boy." After the practitioner left she was sorry and was afraid she had been rude to him. She still continued to think that her right hand did not belong to her. One morning she stated that she had lost two fingers, meaning her rings; she had placed them on her right instead of her left hand. When the rings were put on the left hand and she was asked if it was all right she said: "It is very much better now."

Three months after the onset it was noted that she had been decidedly better for the past week; she recognised her surroundings (home, &c.) for the first time a week previously. She was much more sensible and began to take interest in household affairs. She was much less emotional. She still made mistakes in naming people, but was now conscious that she made these mistakes. She told me so and said it annoyed her. On one occasion the patient told me that she failed to recognise her daughter, who had nursed her all through her illness, when she came into the room, but that she knew her by her voice immediately she began to speak; said that until she heard her voice she did not think she was one of her children. The acuity of vision after correction with suitable glasses was $\frac{20}{20}$. The hemianopsia still continued (see Fig. 5). It was absolute both for light, form, and colours; and I may take this opportunity of saying that it persisted without change until the patient's death. The word-blindness was still complete. She was unable to read a single word. The only letters of the alphabet which she recognised at this visit were "o" and "a." She said: "I see them" (the letters) "but do not seem to know what they are." She recognised pictures quite well, but could not tell the time on my watch. She said the word "of" was "ox"; read the numbers 102 and 60 correctly; said 420 was "420"; read "Edinburgh" as "400"; and could not read the word "powder," but said the individual letters were "g, c, m, n." She wrote her own name and the number 102 correctly when asked to do so. She could not name a knife when it was shown to her. When asked, "Is it a pen?" she replied "No." "Is it a knife?" "No." "Is it a button-hook?" "No" (with emphasis). "Is it a knife?" "Yes." Her condition became at this time

FIG. 5.

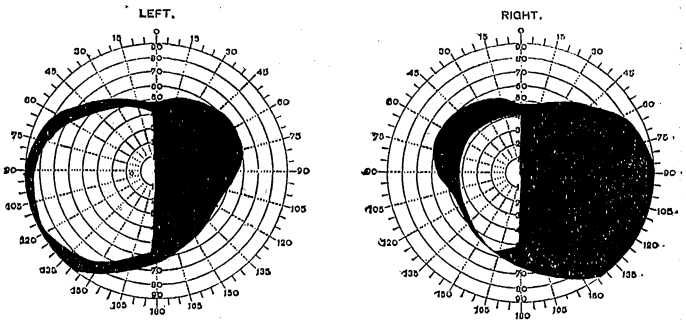

Chart of the fields of vision in this case (word-blindness and hemianopsia) taken three months after the onset of the attack.

distinctly better. She read the figures 8, 10, 50, and 54 correctly; said 102 (which she read correctly at the last visit) was "one hundred and—well, I cannot read the last." She read the words "cat" and "dog" correctly.

Four months after the onset of the attack she wrote me a letter. After writing the letter she was unable to read a word of it. Practically the only mistakes were in punctuation.

Condition a year after the attack.—The patient was at this time looking much brighter. Her friends said that she was quite clear mentally. Her daughter said that she had written several letters; they were well written, well expressed, and correct in every way, but she could not read them after she had written them. Her power of reading was, however, improving. She read the words "Her saints and kings" correctly, and named the letters in these words correctly; named all the letters in "royal" and "Edinburgh" correctly, with the exception of l and h; said l was n, but when told that she had made a mistake corrected herself. Read the number 1886 correctly. For some months after the last note the patient was in a very apathetic condition, apparently the result of an attack of influenza; on recovering from the influenza she was very much depressed, weak, and tottery; would sit for hours together with her head bent forward without speaking. Her medical attendant thought that she was going into deep dementia. The urine now contained a small quantity of pus, but was otherwise normal.

Condition eighteen months after the onset of the attack.—She was now looking very well and bright and for some time past had had no noise in the head; for some time previously she had complained much of this symptom. The urine still contained a small quantity of pus. She admitted that she felt better than she had done since her illness commenced. She answered questions sharply and brightly. Her memory was, however, still very defective for certain things; for example, she could not tell me what she had had for luncheon, or where she had been for a walk in the morning. The day before my visit, when asked what o'clock it was, she read the time on the clock without hesitation, and quite correctly. She had never been able to do so before since the onset of the attack.

Condition two years after the onset of the attack.—She remained very well all the summer. A fortnight ago she was suddenly seized, when out walking, with sickness; had to be carried home; vomited several times during the night and became very depressed, complaining bitterly of the "noise in the head," and saying more than once that there must be something in the room or house causing the noise.

Condition two and a half years after the onset of the attack.—After the last note the patient remained for several weeks in a dull, lethargic condition. She then gradually improved and for the past three months has been extremely

Hosted by Google

well, better in every respect (except reading) than since her illness commenced. She knitted and worked incessantly, but did not make any attempt to read or write. Her idea of locality seemed particularly good. Her reading power remained much *in statu quo*. On examination she was able to spell out some words, but failed to recognise some of the letters. When a word, however long, was spelt out to her, she at once knew what it was. I remarked to her daughters that her spelling seemed very good, and they immediately said that it was quite unaffected and that they were in the habit of referring to her (as they had been in the habit of doing before she was taken ill) on any doubtful point of spelling. She used to be an excellent speller and still retained her spelling power perfectly, though quite unable to read. When I tested her to-day she failed to read "a" and "not." She said that she thought she could read, but she was lazy and did not care to do so. Her eyesight was very good and her inability to recognise letters and words was not due to defective eyesight. There was no change in other respects.

Condition three years after the onset of the attack.—The patient was well all the previous summer, but became duller mentally when the short evenings and cold weather set in. She looked much the same and had not written any letters or attempted to read since the last note.

The patient died four years after the onset of the attack from acute congestion of the lungs and heart failure. There had been no material change in her condition since the last note.

Corrigenda.—Case 1, description of Fig. 1: Instead of "right-sided bilateral temporal hemianopsia," read "right-sided lateral homonymous hemianopsia."—Page 801, left-hand column, thirty-second line from the top, instead of "'pure" agraphia, read "true" agraphia.

Edinburgh.

AN UNDESCRIBED SYMPTOM IN PERITONITIS.

BY WILLIAM HENRY BATTLE, F.R.C.S. ENG.,
ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL AND TO THE ROYAL FREE HOSPITAL, ETC.

So far as I know, the symptom to which I wish to call the attention of the profession has not been described in cases of peritonitis, and must accordingly be a very rare one. There is also a probability that this symptom appears in a late stage of the disease, and indicates a very intense inflammation of the peritoneum.

On the morning of Jan. 19th, 1897, I was requested to see a patient under the care of Dr. Seward in the Colney Hatch Asylum who had developed serious abdominal symptoms. The patient was a man, aged forty-seven years, who had been an inmate of the asylum for three and a half years, suffering from chronic melancholia with a previous history of alcoholic excess. He had had good bodily health until three months before the date on which I saw him; he had then suffered from an attack of hæmatemesis of short duration, the cause of which could not be discovered. He had resumed out-door work and appeared to have been in good health until Jan. 12th, when he had another short attack of hæmatemesis. Three days after this he vomited several times and complained of abdominal pain and constipation; his temperature was 101·6° F., and this was the highest registered during his illness. Vomiting continued at intervals, but no further blood was present in the vomit; the constipation was unrelieved by enemata, the abdomen became distended, and the pain increased. During the night of the 18th the symptoms had become much worse, the vomiting had become much more frequent, and the distension and tenderness had much increased. After the despatch of the message to me a condition of collapse set in, and on my arrival the patient was in a very low state not admitting of operative interference. His condition was as follows: He was lying on his back with his limbs flexed and his head bent forward; he had a sallow, smooth, expressionless face, the eyes and mouth being unduly opened as from muscular weakness; but he was able to understand and answer questions. He was unable to protrude his tongue, which was very dry, beyond the teeth. His extremities were bluish and cold; respiration was rapid and almost entirely thoracic; the pulse was quick, weak, and very compressible. There was frequent vomiting, which was not feculent, but no passage of fæces or flatus per anum. There was considerable distension of the abdomen, a general tympanitic note on percussion, with much tenderness all over it, but no complaint of pain. This tenderness was most marked in the lower epigastric region, so much so that it caused particular attention to be drawn to the part. It was then found that in both groins, extending outwards to the superior iliac spines, was a symmetrical puffy œdema of the sub-cutaneous tissue; that the œdema was limited as regards its downward extension into the thighs by the deep layer of the superficial fascia, the attachment of which was clearly outlined, and that it passed backwards to a slight extent into the flanks. The skin was somewhat flushed in the groins, and wherever the œdematous condition passed there was excessive tenderness; the scrotum was œdematous and very tender; there was no œdema of the legs. For the last two days he had had retention of urine which was relieved by catheter; but the urine was normal and the instrument had passed easily. The condition of the patient was becoming rapidly worse, and although it was highly probable that operative treatment was required to relieve his symptoms it was evident that nothing could be done to prevent a fatal termination which was only a question of a few hours. I expressed an opinion that although the symptoms, without the œdema of the groins, indicated peritonitis, the presence of the œdema made it certain that such an inflammation was there, whatever might have been the primary disease. At the post-mortem examination made by Dr. Bryan, to whom I am indebted for the following account, the diagnosis of acute peritonitis was fully confirmed.

Necropsy.—The post-mortem examination was made seventeen hours after death. The body was found to be well nourished. With regard to the head the calvaria was normal and the dura mater was normal; the pia mater was much thickened and stripped easily; the brain substance was somewhat soft, otherwise normal. The vessels at the base were healthy. There was slight hypostatic congestion of the lungs, otherwise they were normal. The heart was healthy; there was slight atheroma of the aorta. As to the abdomen there was an unusual amount of fat, the great omentum being very fatty and the sub-peritoneal fat generally was in great excess. The large intestine from the anus to the cæcum was much distended; there was a hard mass of fæces of the size of a small orange in the cæcum just at the valve, otherwise the large intestine was empty. The appendix was normal. The small intestines were normal throughout except where a small coil dipping down into the pelvic cavity was affected by the peritonitis described below. The mucous membrane of both the large and small intestines was healthy. There was a local acute peritonitis limited above by the cæcum and the lower part of the sigmoid flexure, affecting the whole of the pelvic cavity. There were recent adhesions between the rectum and bladder and much recent lymph in the neighbourhood of the cæcum. There was much œdema of the sub-peritoneal tissue, which extended along the inguinal canals on both sides into the scrotum. No cause for the peritonitis could be discovered after a very thorough search, which included an examination of the bones of the pelvis. The liver and stomach were healthy, as were all the other abdominal organs with the exception of the right kidney, which was somewhat pale and which had an appearance of some former inflammatory affection.

Remarks.—The post-mortem examination confirmed the opinion which had been given as to the causation of the unusual condition present during life and also demonstrated the correctness of the explanation which had been offered. Some ten years ago I was called upon to perform an operation about midnight for a patient suffering from acute abdominal symptoms which had commenced when he was straining at stool at six o'clock on the same morning. His condition was very bad and it was impossible to find out what had been the state of his urinary functions before the sudden attack of pain at the time mentioned, but he had been to his work on the previous day and was not known to have been ill. When the abdomen was opened in the middle line the sub-peritoneal tissue contained such an excessive amount of fluid that the possibility of a pathological extra-peritoneal rupture of the bladder suggested itself as the most likely cause for the presence of such an amount in that situation. A sponge saturated with this fluid

Hosted by Google

was pronounced by those present to have a distinctly urinous odour. I myself was unable to express any opinion as a nasal catarrh had taken away my sense of smell. Accordingly the peritoneal cavity was not opened, but a puncture was made in the perinæum and a large catheter passed into the bladder to provide for drainage. The man lived but a few hours afterwards. At the post-mortem examination very acute purulent peritonitis, due to the giving way of a typhoid ulcer, was disclosed. It was not, therefore, a great stretch of the imagination to picture a similar inflammatory exudation as present in this patient, with an escape of some of the fluid along the inguinal canals into the groins, and to a less extent into the scrotum. The comparatively small amount of exudation into the scrotal tissues is probably accounted for by two circumstances—(1) the dorsal decubitus of the patient, and (2) the irritating effect of the fluid on the muscular tissue of the scrotum, which was wrinkled as from muscular action of the dartos, and formed a great contrast to the smoothly distended scrotum of the dropsical patient, or that of the sufferer from urinary extravasation. I have mentioned that the œdematous area was excessively tender, to touch it even lightly made the patient start far more than pressure over the abdomen above the level of the extravasation. It resembled in this respect the tenderness near the extreme edge of the advancing area in spreading gangrene.

It hardly appears necessary to point out the difference there is between this form of œdema and that due to cellulitis of the scrotum and groins having its origin in some external breach of surface; the limitation of the exudation by the deep layer of the superficial fascia will clearly differentiate the two, as it also excludes any form of dropsy. Its resemblance to extravasation of urine is much more near, but it does not pass into the perineum, and the scrotum in extravasation of urine, where the fluid is at first of a less irritating character, is very much more distended in proportion to the extent of groin extravasation; the penis is also much enlarged, and there is usually a well-marked history of stricture of the urethra, with proof of its presence, whilst there are no symptoms pointing to peritoneal inflammation. If the urethra had given way in front of or under the scrotum the swelling of the penis and scrotum would be in excess of the other portion of the swelling and the stricture signs would be evident, &c. It is very possible that this condition, although noted, has been ascribed to an exudation through the abdominal wall in consequence of the inflammation of the muscular tissue over a centre of inflammation within the abdomen. It is not unlikely that much of the œdema in cases of localised inflammation about the cæcum has followed the sub-peritoneal tissue in part, and that in an œdematous condition of the subcutaneous tissue of the groin the fluid, anticipating the closer approach to the surface of an inflammatory exudation, has really gravitated to that position after its escape from the inguinal canal in consequence of the position of the patient. To say that such a condition as that described does not occur because some observer of known skill has not noted it, recalls an observation to my mind which was made by the President of the Clinical Society at a recent meeting; this was to the effect that we could not say that a particular symptom was or was not present in any case, although we might think so, if we had not looked for it. I cannot say that this symptom was not present in the patient to whom I have alluded above, in whom the exudation of fluid into the sub-peritoneal tissue was so excessive, because my attention had not been drawn to the possibility of its occurrence and I did not look for it—indeed, the exudation of such an amount of fluid was a surprise to me, but I was informed that a similar exudation of fluid was not uncommonly found in the post-mortem room. If this is the experience of many pathologists, then it is exceedingly probable that the condition to which I have drawn attention is not so uncommon as would at first sight appear to be the case. We have not sufficient data to enable us to form an opinion as to the exact value of this sign, but it is not unlikely that it is one which indicates a more than usually bad prognosis.

Mansfield-street, W.

WILTSHIRE COUNTY COUNCIL.—The agricultural committee of the Wiltshire County Council have recommended the appointment of Mr. I. M. H. Munro, D.Sc., F.C.S., F.C.I., as district agricultural analyst for the administrative county of Wiltshire.

MEDIASTINAL SURGERY.

By H. MILTON, M.R.C.S. ENG.,
PRINCIPAL MEDICAL OFFICER, KASR EL AINI HOSPITAL, CAIRO.

THE abdominal and cerebro-spinal cavities and the organs they contain have been freely explored by the surgeon since he has adopted cleanliness with the most brilliant results. The thoracic cavity and its contents, although frequently the seat of surgical interference, have not received the same attention, and no definite lines of technique have so far been laid down. This is partly due to the fact that the thoracic walls present more mechanical difficulties to the surgeon than the abdominal, and partly to the dread with which interference with most of the thoracic organs still inspires him. Having lately met with a series of cases of intra-thoracic disease in which there arose an urgent demand for surgical interference I determined to try to ascertain whether the general cavity of the thorax must of necessity remain a *terra incognita* to the operating surgeon. Considering the subject in the post-mortem room, the advantages of the median incision—a prolongation, in fact, of the usual abdominal exploratory incision—could not but strike one. So easy is this incision of execution and so considerable is the power of exploration thereby obtained that one is almost induced to hope that future experience may justify the application to it of the term "normal thoracic incision." As a commencement of my experiments I opened some ten thoracic cavities of subjects dead from various diseases, employing, with slight variations, the following method:—1. A long skin incision from the thyroid cartilage to the ensiform cartilage. 2. Exposure by rapid dissection of the trachea down to the notch of the sternum and of the same bone in all its extent. 3. The separation of the fascia from the notch of the sternum as far outwards as the tendon of the sterno-mastoid on either side, keeping the point of the knife absolutely on the periosteum of the sternum so as to avoid injury to veins, &c. 4. The separation with the finger tip of the posterior surface of the sternum, just below the notch, from the tissues lying beneath it, these latter being displaced backwards. They consist principally of the innominate vein and artery, the trachea, and many nerve branches and plexuses. 5. An incision with the saw along the middle line of the sternum from notch to ensiform cartilage, not implicating the latter and not quite cutting through the whole thickness of the bone. It is to be noted here that the thickest and hardest portion of the bone is at its upper end. This must be thoroughly divided, the vein and other underlying structures being protected by a finger inserted behind the sternum. 6. The complete separation of the two halves of the sternum I have carried out in two ways. In some cases I have commenced at the sternal notch, in others just above the ensiform cartilage. The second method has the advantage that the first part of the separation, which has to be done with but a very obscured view of the deeper tissues, takes place at a situation where the mediastinum is wide. There is less danger consequently of wounding the pleura, and by inclining the incision to the left this danger is still more averted. In the operation on the living subject I followed this method, but still I cannot say that I found in my preliminary operations on the cadaver any great superiority of the one over the other method. Whichever method is followed great care is necessary in separating the two halves of the sternum to avoid injury of the deeper tissues. In beginning from the lower end of the sternum the ensiform cartilage must be separated first from the sternum. This in young subjects can be done with the knife; in older subjects I have used scissors or bone nippers. Strong, broad-hooked retractors are now inserted into the halves of the sternum along the line of incision and moderately firm traction outwards and slightly upwards applied to them. The ensiform cartilage is now thoroughly separated from the sternum. There is but very little possibility of opening the peritoneal cavity in doing this, and even should it occur it is of no importance. With a retractor the tissues lying under the line of separation of the ensiform cartilage and the sternum are now displaced backwards, great care being taken to work quite close up to the posterior surface of this bone. Either with knife or scissors the saw-cut is carried right through the bone, extending upwards to the limit of separation of the deep

Hosted by Google

tissues. Firm retraction is made on either side and a further extent of tissues displaced backwards from the sternum, and the incisions through this latter completed to the same extent. This process is continued with due care until the whole bone is divided. In working from above the process is simple, but perhaps more risky. After thoroughly displacing backwards the deep tissues from behind the sternal notch the upper portion of the bone is completely sawn through so far as the action of the saw can be thoroughly guarded by the finger. The incision along the middle line of the sternum is then completed in the same cautious way as a trephine is usually applied to the cranial bones. A blunt chisel is inserted along this incision, and partly by the twisting of this and partly by the action of the retractors the two halves of the sternum are forced apart, any necessary assistance being given by careful incisions with the knife. This method I have not carried out on the living, but I believe it to be practicable. 7. Exposure of the mediastina. Firm traction on both halves of the sternum is now sufficient to separate them to the extent of one centimetre, enough to expose any tissues resisting separation to a greater extent. In the cadaver the principal resistance is caused by the ligamentous tissue at the back of the sternal notch. These fibres lie immediately above the innominate vein, but may easily be separated from it and be carefully divided. Another point of resistance is usually at the lower end of the sternum. This may be safely divided, and it will then be found that after dividing any other resisting fibres the two halves of the sternum may be separated to the extent of from five to six centimetres and the anterior mediastinum be thoroughly explored. Crossing the top of this space are seen the innominate vessels, behind them the trachea. The latter can be explored by the finger down to its bifurcation, and can be seen to the same extent if the vessels are thoroughly retracted. Below the vessels are seen the two pleuræ and the pericardium. The latter is a firm structure, and not likely to be injured during the exposure of the mediastinum; the former are very delicate in texture, but may with care be left uninjured. In only one of my experiments was the pleura opened, and that was due to carelessness in an emphysematous subject. Once the anterior mediastinum is exposed the exploration of the median and posterior mediastina is a simple matter, and is effected by separation with the fingers of the pericardium from the right pleura. The closure of the mediastinum after exploration is simplicity itself. Six strong silver wires passed first through the skin, then through holes bored at equal distances in both halves of the sternum, and then through the skin again, were sufficient to firmly re-unite the sternum, and in the living subject could be easily removed after cure. A gauze plug situated above the sternal notch and another, if necessary, at the lower end of the sternum would supply sufficient drainage, and a skin suture would complete the closure of the wound.

The results of my experiments on the cadaver sufficed to show the possibility of opening the mediastina through a median incision without injury to any vital structure. I have to thank Dr. Ruffer, the director of the Pathological Department of the Cairo Medical School, for much kindness and assistance. It was now necessary to ascertain what difficulties were to be met with in operating on the living subject. The important questions to be decided were what effect would the opening of the mediastina have on the respiration and circulation; and, further, would the necessary dissection be attended by any considerable or uncontrollable hæmorrhage. The division of the sternum could not fail to seriously affect, if not to arrest, costal respiratory action, but it was to be anticipated that the diaphragmatic action would continue and would suffice. It was, moreover, possible that atmospheric pressure acting on the outside of the pleura might detach it still further from the bony framework of the chest. Precautions were taken, however, to meet these complications should they arise, an apparatus for artificial respiration being prepared with an indiarubber covered glass tube to fit lightly into the trachea. Any considerable ill effect on the circulation from opening of the mediastinum was not anticipated, and the result of experiments justified this assumption. The animal chosen was a goat, as being the largest easily obtainable, and the operation was performed in the Physiological Laboratory of the Cairo School of Medicine. (I wish here to express my gratitude to Dr. Wilson, the Professor of Physiology, for great assistance and many useful suggestions.) The animal was chloroformed completely and the thorax shaved. The division of the sternum was a matter of some difficulty, as I did not know its exact shape or relative anatomy. It proved to be very narrow, much more solid than the human sternum, and curved at an acute angle. Moreover, after it had been cut through it became evident that in the goat there is practically no mediastinum, so that the incision in the sternum produced almost of necessity wounds of both pleuræ. An immediate collapse of both lungs was the result. Tracheotomy was performed at once, the glass tube inserted in the trachea and artificial respiration carried out with the bellows. During this process the heart's action became irregular and rapid, but directly respiration was re-established the circulation became normal and remained so during the whole operation. The artificial respiration rapidly produced apnœa, and all respiratory action on the part of the animal ceased, to recommence, however, whenever the artificial respiration stopped. The various mediastina could now be thoroughly explored, and it was found that the loss of blood both during the division of the sternum and the separation of the pleuræ was immaterial. The heart could be thoroughly explored—the pericardial sac was not opened—and it proved very refractory to any manipulation. A firm grasp on it produced only a temporary irregularity in its action, and immediately on release it resumed its usual rhythm. The condition of the animal remaining very good, I proceeded to close the wound. The pleuræ were closed as far as possible with a continuous silk suture, the sternum re-united with wire sutures, the skin with a continuous silk suture, a gauze plug was placed above the sternal notch, the tube was removed from the trachea as soon as normal respiration had established itself, and a tight dressing was applied round the animal's neck and chest. Half an hour later the goat was walking about the room; it ate and drank, and voided fæces and urine. A short time afterwards it was killed in order to avoid needless suffering.

Having convinced myself that the opening of the mediastina did not of necessity inflict such injury as to entail the death of the individual, I determined to attempt similar operative interference for the relief of human suffering. I have had lately under my care three cases in which the question of surgical interference arose. In the first two the conditions were so entirely against a successful issue that I decided not to make any attempt. The first was a case of mediastinal tumour pressing on the innominate vein, producing œdema of the face, neck, and arm, and on the trachea producing gradually increasing dyspnœa. On first seeing the patient it was evident that no hope was left of curative treatment, as there was certainly deposit in the liver and probably in the lungs, and the mediastinal tumour was probably glandular in nature and of secondary malignant growth. I could do nothing but await symptoms of urgent dyspnœa and attempt to relieve these by tracheotomy and the insertion of a long tube. The symptoms eventually arose; tracheotomy was attempted, and the patient died on the table. The second patient is still alive, and it was with a view to operative interference in his case that I first commenced my experiments. He was admitted to the hospital suffering from urgent dyspnœa of some days' standing, his condition being such that tracheotomy was performed at once by my Egyptian assistant, who was of opinion that the case was one of syphilitic laryngitis. Finding that tracheotomy gave no relief he sent for me. I could find no sign of any mediastinal tumour or other cause of pressure on the trachea, but the obstruction being evidently some distance below the tracheotomy wound I passed a six-inch flexible tracheotomy tube down the trachea, and passed an evident obstruction with immediate relief to the breathing. Careful examination a few days subsequently afforded no definite signs whatever as to the cause of the obstruction. In about fifteen days, however, infiltration began to appear above the sternal notch, and to-day, some two months from the date of tracheotomy, the whole base of the neck is one infiltrated sarcomatous mass. I may say that, in spite of an absence of any syphilitic history, iodide and mercury were thoroughly tried. In the earlier days after tracheotomy the case seemed eminently fitted for mediastinal exploration, but the appearance of infiltration at once set aside all possibility thereof.

My third case was a more favourable one, and after much consideration I operated on the patient on Jan. 25th, 1897, and to-day (Feb. 6th) he may be considered as practically cured. He was an Egyptian fellah aged about twenty-five years. No family history was obtainable. He had suffered for some months (according to his account) from pain and swelling in the sternal region, with increasing incapacity for

Hosted by Google

work, and some cardiac palpitation, with pain and oppression in the epigastric region and shortness of breath on exertion. Examination disclosed a very prominent sternal region, the skin over it being infiltrated and tender to pressure. The sternum was the seat of a tumour which occupied nearly its whole length and which extended on either side into the rib area. The tumour was hard in the greater part of its area, softer and tender at others. On percussion the whole tumour area was dull and measured some twenty centimetres in length by seven in breadth. The tumour was elevated about three centimetres above the normal level of the sternum. The heart dulness could not be separated laterally from that of the sternum, but the apex beat was displaced outwards rather more than two and a half centimetres. The heart sounds were normal. The chest expanded well and the breath sounds were normal, except that behind the first part of the sternum the tracheal respiration was harsher than usual. There were no other signs of pressure on the trachea and no signs of pressure on the veins. There was no enlargement of the cervical glands; all the organs of the body were healthy. The pulse was 82 and the temperature was normal in the morning and 37·3° C. at night. Tuberculous caries and necrosis of the sternum being a common disease in Egypt, there being no signs of any sarcomatous growth, and syphilis being absent, a diagnosis was made of infiltrating tuberculosis of the cancellous tissue of the sternum and possibly of the mediastinal glands. The patient being incapacitated from gaining his living and his general condition being good, it was decided to attempt his relief by operation. He was chloroformed and an incision made from the cricoid cartilage to the ensiform cartilage, the skin being reflected on either side and the trachea and sternum exposed. The sternum was soft and friable all over, and larded, as it were, at various points with cheesy, tuberculous deposits. I have on several occasions seen a similar condition in the tibiæ of tuberculous children; the whole bone is greatly thickened and at the same time porous, and presents at various points deposits the size of a bean of tuberculous, caseating débris. The condition exactly resembles that often found in strumous glands. The sternum was next carefully divided from the ensiform cartilage and was found to be very porous and greatly thickened. This was really the most difficult part of the operation. It would have been easier to have split the ensiform cartilage, but I wished to spare as far as possible the insertion of the diaphragm. The mediastinal tissue underlying the end of the sternum was then depressed and the sternum split with saw and chisel, working little by little until the bone was divided in its whole length. It was found thickened to the extent of three centimetres in some parts and studded with caseous deposits. In dividing the sternum it was often necessary to remove large portions of infiltrated bone with the gouge. On carefully examining the two halves of the bone they were found to be so infiltrated with tubercle that the whole sternum had to be removed bit by bit with the exception of the upper portion—a centimetre and a half in length—which was simply divided. This division was necessary in order to remove two enlarged caseous glands situated behind it in the mediastinum. After the division of the sternum and separation of its two halves this removal was effected with the greatest ease, the glands peeling as readily off the innominate vein as they would have done off, say, the internal jugular vein. During the whole operation there was remarkably little hæmorrhage; half-a-dozen arteries were seized with pressure forceps and a few oozing points were touched with the cautery. At no moment was the heart's action troubled. The costal respiration ceased on the division of the sternum, but the abdominal respiration was maintained with complete regularity. The wound left by the operation was very large—larger, of course, than it need have been in most mediastinal incisions, in that nearly the whole of the sternum had been removed on account of tuberculous deposit. The sides of the cavity were formed by the ends of the costal cartilages and the tissues in between them, at the lower end of the wound was the ensiform cartilage, at the upper end the trachea (exposed in case tracheotomy became suddenly necessary) and the innominate vessels crossing it. The floor of the cavity was formed by the mediastinal tissue, on either side were the pleuræ and on the left side the pericardium. The pleuræ were not adherent to the lungs or the pericardium to the heart, the movements of all three organs being perfectly free. Although aseptic precautions had been taken, I did not dare, considering the tuberculous condition of the bone, and in spite of the total absence of pus, to attempt complete closure of the wound. I considered it safer to plug with sterile dermatol gauze, which remained unchanged for forty-eight hours. During the whole of this time the patient's condition was most excellent: he had but little shock, his temperature never exceeded 37·1° C., his respirations were from 24 to 26 and entirely abdominal, his pulse was from 80 to 90, and he slept without morphia. On the second day after operation chloroform was again administered and the plug removed. It was found that the ribs had come together to a very considerable extent, so that the pericardium and pleuræ, though still visible, were but little uncovered. The wound was quite clean, and it was decided to close it. A thin strip of gauze was laid along the bottom of the wound to serve as a drain, and the soft tissues were closely united from one end of the wound to the other with a continuous wire suture, a small opening being left for the gauze to protrude above the sternal notch and at the lower end of the wound. Two days later the temperature rose to 39 4° C., and the respirations to 36, and there was a slight attempt at coughing. This constituted the only real difficulty in the whole progress of the case. The endeavour to cough was very distressing to the patient, and was practically unavailing. The feeble movements necessary for respiration had been carried on without difficulty, but the violent expulsive action of coughing could not be carried out with a divided sternum. A purgative was given, and the dressing changed. On removing the gauze plug a slight retention of secretion, sero-purulent in nature, was discovered. The escape of this secretion was followed by a fall of temperature to normal, and a cessation of the desire to cough. Three days later there was a rise in temperature to 39·1°C.; a purgation was followed by immediate cessation of these symptoms. To-day the wound is completely dry, the gauze has been removed, and the patient is entirely convalescent. I shall keep him in bed, however, for another thirty days at least, in order to allow of thorough consolidation. His costal respiration is gradually re-establishing itself, but has not yet returned to the normal. I have to thank Dr. Sandwith, who saw all three cases with me, and who was present at the second operation, for much assistance and advice.

The practicability of mediastinal exploration has been, I think, established by the above case; experience only can show whether the risk thereby entailed is greater than the profit obtainable. In Cairo we have unfortunately but little literature available, and I cannot be sure whether a similar operation has ever been performed. Péan has, I know, removed a portion of the sternum to get at a mediastinal growth, operating in a diving-bell within which a pressure of two atmospheres was maintained. This information I owe to an assistant at the operation, and I believe that a description is to be found amongst Péan's Cliniques. The operation presented great difficulties and the patient, I believe, died on the second day. It is evident that in an operation on the mediastinum there must always be a danger of wounding the pleura; but such a wound, followed as it naturally would be by a collapse of the lung, need not of necessity entail a serious accident. Tuffier and Hallion have shown[1] that the dog's pleura can be freely opened without ill effect, and I have myself opened the pleural cavity with impunity on several occasions when operating on liver abscess or tumour. Should any difficulty be anticipated, it is a simple matter to carry out artificial respiration with the bellows through a tracheotomy tube. In my experiments I have found that for this a Trendelenburg's cannula is by no means necessary. A bent glass tube covered at its lower end with an indiarubber tube of a smaller diameter and projecting half an inch beyond the glass is quite as effectual and much simpler. Tubes of various diameters should be at hand, and the one inserted which just plugs the trachea. This is quite sufficient to prevent any escape of air at the slight pressure necessary for respiration. If it be established that median thoracic incision is a fairly safe procedure, I have no doubt that it will constitute the most generally useful route to the thoracic organs. And if once a safe route is established a great field for surgical interference lies open. That the lungs are amenable to surgical interference has been frequently proved, and many surgical procedures, from the removal of a foreign body from a bronchus to the extirpation

[1] Semaine Médicale, 1896, p. 480 et 503.

Hosted by Google

of the whole lung, may some time or other be classed amongst established operations. Heart surgery is still quite in its infancy, but it requires no great stretch of fancy to imagine the possibility of plastic operations in some, at all events, of its valvular lesions. That the heart is tolerant of wounds and injuries has been proved over and over again, and I see no reason why it should not be equally tolerant of a deftly guided scalpel. Surgery of the large thoracic vessels is by no means modern, and an improved technique should render interference with them much easier and much surer. Not only will the anterior mediastinum with its not uncommon growths, innocent and malignant, lie open to us, but also the median and the posterior, and operations on the œsophagus, the thoracic duct, and the great nerve trunks of the pneumogastric and sympathetic may come within our range. Briefly stated, should median thoracic section establish itself as a safe operation the last great cavity of the body and its contents lie open to the surgeon's hand and knife.

Cairo.

REMARKS SUGGESTED BY DR. CLIFFORD ALLBUTT'S PAPER UPON ALBUMINURIA IN PREGNANCY.

BY LOVELL DRAGE, M.A., M.D. OXON.

To a working obstetrician like myself great pleasure was given by a perusal of this paper,[1] so full of thought and interest. In a paper upon Puerperal Fevers published in THE LANCET on Feb. 24th and March 3rd, 1894, the following sentence will be found: "The characteristically original and able work of the late Dr. L. G. Wooldridge is suggestive of the idea that the full elucidation of this subject will be derived from chemical investigations, and especially those in connexion with the various conditions of the blood." When I was writing these words I had not the knowledge of such work as I now have, but it was a matter of certainty in my mind that in the case of the puerperal fevers there was a great deal more to be taken into consideration than the simple dictum that puerperal fevers were the result of dirt and nothing else. This dictum, supported as it has been in public by gentlemen in the same position as its author with a view of promoting certain legislation, is one strenuously to be combated, and it was my endeavour in the paper which I wrote in 1893 and published in 1894 in THE LANCET to prove that there were conditions connected with the mother to be taken into account in considering the causation of all puerperal fevers. At that time I was very much taken up with the consideration of the causation of puerperal thromboses. Since then a large experience of such cases and a large experience of women who were likely to suffer from eclampsia have led me to think more and more in the same direction as that in which Dr. Allbutt points, though without the same exact knowledge of the chemistry involved.

What is the basis upon which my thoughts rest? To take the subject of Dr. Allbutt's paper first, and a case which recently gave me grave anxiety before delivery. The history of the patient: Five deliveries, one child stillborn; a great many miscarriages; puerperal sepsis twice, once leading on to parametric abscess; at the last delivery eclampsia. The patient was about thirty-five years of age, and at my first examination there was albumin in the urine. There was also general anasarca, well marked but not excessive. This history was sufficient in itself not only to arouse special interest, but special anxiety for the result. The patient was therefore placed upon a treatment of purgation accompanied by treatment by iron, and a diet in which milk was pushed. Two scruples of compound jalap powder and one of the acid tartrate of potassium were given in the first place without result. This was followed by an active purgative pill, which produced an evacuation. Subsequently the patient took, night and morning, a drachm of Epsom salts and fifteen drops of the liquid cascara extract with some ginger. The result was satisfactory, for two or three liquid actions of the bowels resulted every day. Besides this, a mixture containing the freshly precipitated oxide of iron was given thrice daily. The labour came on at the end of the eighth month, and was terminated so far as the child was concerned before my arrival. The albumin in the urine at once diminished, and the patient made an excellent recovery. The treatment, which is a time-honoured one in this practice, is one which I have carried out because it is based upon a working hypothesis. Purgatives which produce free watery evacuations have an action upon the blood. What that action is cannot be definitely stated, but Dr. Allbutt's paper indicates a possible, if not a probable, one, and the same remark applies to the action of iron salts.

Other conditions connected either directly or indirectly with pregnancy seem to me to support Dr. Allbutt. First, the œdematous condition not infrequently met with in pregnant women, with no albumin in the urine and with no eclampsia. These women, although often so swollen that they cannot wear their rings, do not suffer in health; but surely this is a condition which we can connect with the more serious one. Secondly, there is the condition which the late Dr. Matthews Duncan described in his lecture upon Hydroperitoneum—the collection of fluid in the abdominal cavities of elderly women who have borne children without any sign or symptom of disease of organs. Here, again, is a condition difficult of explanation no doubt, but eminently one to be considered in connexion with the subject. Thirdly, there are the various conditions connected with the vomiting of pregnancy. The late Dr. Matthews Duncan fully recognised the fact "that the condition of the blood is probably a chief part of the cause of the proneness of women to disease of the kidney and uræmia," the condition of the great glands being, in his opinion, "probably the cause of their proneness to further dangerous stages of parenchymatous degeneration, chiefly of the liver, but also of the kidneys and other organs." He looked upon the parenchymatous degeneration of the great glands as the first stage of the serious cases of vomiting in pregnancy, the degeneration present even in healthy pregnancies. It is not very difficult now to suggest the link in the causation of such troubles if Dr. Allbutt's theory is accepted. Dr. Duncan, with his great shrewdness and unrivalled experience, knew that the conditions connected with certain cases of the vomiting of pregnancy were not due to nervous causation, but he did not know what is now known of chemical conditions connected with the blood. He pointed to the liver as being the organ most at fault, and in this he was doubtless correct; the knowledge of his day showed that there were changes in the structure of that organ, but it did not show that there were chemical substances circulating in the blood of pregnant women which might account for the change in its structure as well as for that in other glands. His teaching on this subject is, however, only part of the debt which his pupils owe to him, and it is a matter of interest to read Dr. Allbutt's paper with that teaching present to the mind.

Now, to take the subject of thromboses. These have occurred in my practice at times varying between ten days and the fourth week after delivery, with no rise of temperature or any indication of sepsis before the date of the attack. It certainly appears unlikely that there is a connexion between these attacks and sepsis at the time of delivery, and an explanation based upon the theory propounded by Dr. Allbutt appears more reasonable and is certainly that to which I incline. The one predisposing factor at the time of delivery which has been brought forward as conducive to these cases is hæmorrhage, and in none of the three cases which have occurred in my practice has hæmorrhage been present of such a character as to call for remark. The late Dr. Wooldridge's paper on Auto-infection in the Causation of Cardiac Disease certainly leads me in the direction of belief that these thromboses are due to the presence in the blood of some chemical substance peculiar to the blood of puerperal women. It also lends support to Dr. Allbutt's paper.

Finally, what evidence will a study of puerperal fevers provide? Let us put aside once for all statistics, which can be of no possible utility in the consideration of causation. As every working obstetrician knows full well, it is impossible to forecast the progress of a patient during the lying-in period. The cases which have demanded great attention and caused anxiety during the actual labour are not those which, as a rule, give further anxiety, and I include the third stage of labour, which is the critical one so far as puerperal fevers are concerned. It is the critical one because, in the first place, of the difficulty of certainty as to complete removal of all decidual remnants,

[1] THE LANCET, Feb. 27th, 1897, p. 579.

Hosted by Google

and, in the second place, of the chances of hæmorrhage. The latter is not a difficulty which has occurred during my presence at a case, although I have lost a patient some time after delivery at which I was not present and do not know the details of what actually occurred. Some patients habitually lose more blood than others, and others perhaps lose more than they can afford to lose, even when only what may be called an ordinary loss occurs; some begin to lose dangerous amounts of blood after the departure of the accoucheur. The chances of dangerous hæmorrhage, therefore, have always to be reckoned with.

Excluding the tears of maternal tissues, which may always occur whether the labour is naturally effected or not, there is no danger so great as the detention of decidual remnants. Here is a danger of no small kind to the patient, and one which presents itself in no small proportion of labours, however great the care of the accoucheur. I know few matters which give me greater anxiety than the consideration as to whether the uterus is completely evacuated. Even if a complete exploration of the uterine cavity is undertaken in case of serious doubt no certainty can be arrived at. It has frequently been a matter of great surprise to me that the subsequent progress of events has proved that my fears were without foundation. On the other hand, when I have felt satisfied in my own mind perhaps a piece of membrane has come away afterwards without the slightest sign of disturbance, or a rise of temperature has led me to douche the patient and wash the offending material away, and in a few cases to afterwards explore the uterine cavity, and to remove with finger-nail or curette what should have come away during the third stage of labour. Such experiences have led me more and more to think of the reason why in some patients even large pieces of placenta are sometimes left in the uterus for months, and no symptoms of sepsis appear, while in others the presence of even a small shred only of membrane will produce such symptoms—and I include symptoms which to some might appear too trivial to be thus dignified. I do so because it is by the careful watching of the lying-in patients that puerperal fevers, those which are capable of resulting in death, or at all events in crippling for months, can be nipped in the bud.

No doubt the present craze is to think that puerperal fevers are the result solely of dirty methods and direct infection. In a practice where labours are looked upon as surgical operations, and the same care is taken in the one case as in the other, it is possible to eliminate all cases due to such causation, but it is not possible to eliminate the others although it is possible to prevent any serious aspect appearing. Now some have invoked conditions of sanitation to account for puerperal troubles. In our practice here during the last eleven years nearly 1200 women have been attended under all sorts of conditions—the best and the worst possible. I have never yet been able to connect these conditions with symptoms of sepsis; indeed, if I were to hazard a rough opinion it would be to the effect that it is the women who come to their labour under the more favourable conditions who are most liable to sepsis. Dr. Allbutt's paper provides an explanation. The women of the richer classes are, I believe, in comparison worse fed and consequently worse nourished than their poorer sisters, although they have everything that money can command. Not only so; in many cases they are worse fed in the first few months of life, although this is not due to lack of food, but to imperfect method of feeding. The children of the poor die from inferiority in methods of feeding sometimes, from inferiority of quality frequently, and from both combined frequently. The children of the richer classes are more often brought up alive certainly, but crippled in health, from imperfection in the method of feeding.

I cannot estimate the amount of harm which is done by the imperfect methods adopted in the artificial feeding of the children of the richer members of the community, but I know that it is very considerable. The resisting power to disease in this class is lessened at the commencement of life, and is not increased as life goes on. It is a matter of no surprise to me, then, that at the time of labour amongst the richer classes the resisting power to sepsis is less than it is in some of their poorer sisters. However this may be, the fact remains that puerperal sepsis appears in one degree or another even in practices where every care is taken to prevent direct infection and to remove the nidus which may become the seat of infection, and it appears to me that Dr. Allbutt's paper is based upon scientific facts which help to explain many of the problems which present themselves to working accoucheurs, and not to explain them only, but to provide a working hypothesis for treatment. Infection to the superficial eye is a matter capable of easy explanation, but when any attempt is made to account either for the vagaries of epidemics or for sporadic outbreaks of infective diseases, or for the progress of epidemics, or for their origin, superficial theories are found curiously deficient. So far as puerperal fevers go, those caused by direct infection can now be separated from those which are not so caused, and Dr. Allbutt's paper is very useful in pointing to the conditions to be dealt with outside direct infection. The fact, however, remains, that lying-in women are from the conditions present with them, irrespective of the actual delivery and those the result of delivery, especially liable to infection. The mind of the accoucheur should not only therefore be employed in dealing with the latter, but should be alive to the various physiological conditions which are part of the problem. This fact is recognised in a half-hearted manner by some sanitarians—e.g., Dr. Williams, in his paper read before the Epidemiological Society upon Puerperal Mortality,[2] attributes the high mortality existing in Wales from puerperal troubles to the conditions under which the women live, though it is quite obvious that his enthusiasm for legislation causes him to put this factor on one side to a great extent when he comes to consider the causation of puerperal mortality generally. Dr. Williams, in dealing with one epidemic, states that a number of cases attended by infected midwives escaped entirely. Surely the women who thus escaped did not do so owing to the care of the midwife any more than the women who show signs of sepsis in the care of accoucheurs need necessarily be directly infected by the want of antiseptic precautions with which medical men at large are charged by the *élite* of the Obstetrical Society of London.

Hatfield.

SOME UNUSUAL AFTER-EFFECTS OF STRYCHNIA POISONING.

BY N. B. DARABSETH, M.B., C.M. ABERD., M.R.C.S. ENG.

SEVERAL features of interest are presented by the following case which occurred in my father's practice and which exemplifies some unusual after-effects of strychnia poisoning.

In June, 1895, a man consulted us on account of pain and spasms in his upper and lower extremities, accompanied by occasional twitchings of the muscles of the face. In October, 1892, he had been poisoned by strychnia, the dose taken having been about twenty grains. He was at once given a large quantity of snuff and water, which immediately caused free vomiting. My father saw him about half an hour after the poison had been taken. The man was then suffering from severe spasms of the whole body and opisthotonos, and was unable to swallow. Inhalations of chloroform were kept up from 10 P.M. until the following morning, being given whenever the spasms came on; subsequently, when he was able to swallow, a chloral and bromide mixture was given by the mouth. The patient recovered perfectly from the immediate effects of the poison and returned to his work in the ensuing week. In May, 1895, two and a half years after the poisoning with strychnia, my father was again sent for, and found the patient suffering from spasms in his limbs and back; the attack, however, was not very severe and passed off under the use of chloral and bromide. It was practically impossible to obtain a proper history of his condition during the period which had elapsed since the poisoning. He said that for the first six months he was fairly well, although weak and sore; then he once got wet by exposure to rain, and from that day he suffered in his limbs and back from pains which were supposed to be rheumatic both by himself and by several medical men who treated him. In June, 1895, according to my notes, his condition was as follows. He was twenty-eight years of age, had an anxious look, and of late had been slightly dull and forgetful and very languid. He complained of aching pains and formication in both the upper and lower extremities and of fatigue on the slightest exertion. He had peculiar sensations in his limbs

[2] THE LANCET, April 18th, 1896, p. 1067.

Hosted by Google

sometimes as of burning, at other times as of sitting on an ice-cold seat. In the upper extremities he often felt as if an insect was running with great rapidity down his arm to the fingers; sometimes the sensation was as if the insect stopped half way. Some of the muscles, such as the deltoid and the deep muscles of the back of the neck, were in a constant state of contraction, so that they felt hard; his walk was erect, with the head slightly thrown back. He complained of pain in the shoulders and in the back of the neck and head. No actual spasms in the limbs were noticed during the daytime, but while walking he used to feel his legs start up quickly, which made locomotion easier for him, and the muscles of his face sometimes twitched whilst he was in the act of speaking, especially the orbiculares palpebrarum and the dilators of the nose; he always felt tired after even a short walk. The right arm was harder over the deltoid and also larger by half an inch than the corresponding portion of the left arm. At night he was generally restless and subject to sudden startings in the legs, hands, or back, which had the effect of waking him if he happened to be asleep. Chloral gave immediate relief, and he could not sleep without it. The spasms did not cause cramps, but came on in jerks like electric shocks, and generally occurred either when he was engaged in some work or else when he was asleep. When he was sitting quietly or talking his fingers would become abnormally extended. The patellar reflex was exaggerated. The pupils and optic disc were normal, and he had no nystagmus or headache, although he suffered from pain in the back of the neck due to the contraction of the muscles. His gait was quite normal; he could also stand with feet close together and eyes closed, and there never was any weakness in the legs, but only a feeling of fatigue as if from overwork. He was constantly under the impression that he would become paralysed, which made him very anxious and melancholy. The only drugs that gave him immediate relief were chloral and bromide, but the effect was only temporary and great depression ensued. Belladonna, gelsemium, physostigma, and ergot were successively tried, but they caused additional spasms or tremors, and after three or four days' trial of each the patient refused to continue the treatment. Tincture of belladonna was again tried in two-minim doses and gradually increased to fifteen minims three times a day, after five months of which treatment, combined with tonics such as iron and quinine, the patient gradually improved. The shocks and spasms became gradually less, and by the month of November the muscles of the arm and back of the neck were relaxed, there were only very slight and occasional attacks of spasm at night, and the patient was consequently able to sleep well. I last saw him in March, 1896, and found him comparatively well and cheerful. He said that he still felt shocks occasionally, but he was able to attend to his work and even to take long walks and play cricket.

I believe that the pain and spasms were due solely to the overdose of strychnia, that they must have commenced not long after the immediate effects of the poison were recovered from, and that they were the symptoms which were mistaken for rheumatism, not only by the patient, but by some of his medical advisers unaware of his previous history. I have, however, not read of a poisonous dose of strychnia causing such symptoms continued over so long a time, for, ordinarily, if the case does not prove fatal the patient recovers quickly without experiencing any after-effects. It is very difficult to understand why the symptoms should persist so long. I believe that the very large dose which was taken caused congestion of the spinal cord, and that this passing into a chronic stage gave rise to these reflex symptoms. Belladonna was the only drug which seemed to be useful; it probably acted as a spinal sedative. Ergot was given with the expectation that it would relieve congestion, but it caused more spasms and had to be stopped after three days. The patient is certain that no medical man gave him strychnia or nux vomica; he always read the prescriptions, and said that what was ordered was generally iodide of potassium.

Bombay.

PROPOSED COTTAGE HOSPITAL FOR WESTBURY (WILTSHIRE).—A committee has been appointed to formulate a scheme for the provision of a cottage hospital for Westbury and neighbourhood to commemorate the Queen's Diamond Jubilee, for which purpose Mr. W. H. Laverton has promised a site.

CASE OF CONGENITAL MALFORMATION OF THE NOSE.

BY W. R. H. STEWART, F.R.C.S. EDIN., M.R.C.S. ENG.,

SURGEON TO THE EAR AND THROAT DEPARTMENT, GREAT NORTHERN CENTRAL HOSPITAL.

A MAN, aged twenty-five years, was sent to the Great Northern Central Hospital by Dr. Buck. The patient stated that he had been in his present condition as long as he could remember, and had been told that a tumour had been removed from his nose when an infant. He applied for relief, being unable to obtain employment owing to his disfigurement. On admission a deep cleft was found situated in the middle line of the nose running down from the nasal bones to the upper lip and completely separating the nose into two halves, the tissue in the cleft being cicatricial. Under chloroform, the anterior nares having been plugged with blue wool, an incision was made down the middle line from the fronto-nasal junction to the upper lip. From this latter point branch incisions were carried to each tip, and the skin, which was very adherent, was dissected well back. The

halves of the septal cartilage were found to form two distinct septal cartilages, the right being the larger. The bottom of the cleft was filled with dense, very hard bone, and at the lower part greatly thickened cartilage. The bony portion was with some difficulty removed by gouge and bone forceps and the cartilaginous portion carefully pared down. The two cartilaginous halves of the septum were then released as much as possible from their bony attachments and brought together with deep silk sutures. Superabundant skin was then cut away and the flaps were carefully brought together with horsehair sutures. The patient made a good recovery and has now a very presentable nose.

This malformation is, in my experience, unique. The formation of the septal cartilage is due to the coalescence of the nasal laminæ of the lateral nasal processes. This coalescence was evidently prevented by the formation of what was no doubt a dermoid cyst. An excellent cast, taken by my colleague, Mr. Mower White, is in the museum of the hospital.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE ASSOCIATION OF SLOW PULSE AND SYNCOPAL ATTACKS.

BY W. ELLIOT RISDON, M.D., B.S. LOND.

IN this connexion the following brief notes of a case which presented some difficulty during life may possibly be of interest.

The patient, a professional man, aged thirty-eight years, of athletic habits and previous good record, was suddenly seized with faintness whilst quietly walking along the street. When first seen he appeared to be dying, but after an hour's treatment he rallied. His heart was then carefully examined. The cardiac impulse was in the normal situation and the sounds were free from murmur; the action was regular, with a pulse of 70 per minute. On inquiry he stated that this was his normal pulse-rate and that he had never previously had any indication of cardiac weakness. After resting for some hours in the recumbent posture his circulation appeared so satisfactorily re-established that it was thought possible to move him with safety. On sitting up, however, his heart again failed and his condition became critical. After remaining pulseless and deeply unconscious for two hours an improvement again took place and the pulse gradually became of good force, beating from 24 to 30 per minute. There were marked pallor and slight coldness of the extremities, but no pain. The respirations were 14 and the urine was normal. After remaining in this condition for some time the pulse was noticed to become intermittent. This was at first only occasional, but soon became more frequent until there were from ten to twelve dropped beats in succession, the heart resuming with normal force after an interval of twenty or thirty seconds. During this interval there was brief loss of consciousness with slight tonic spasm of the muscles of the face and limbs and dilated pupils, and no sound of ventricular contraction could be detected. The case terminated fatally three days later, but there was no material change in the character of the symptoms, the pulse remaining abnormally slow to the end.

Necropsy.—On post-mortem examination the left ventricle was found to be somewhat hypertrophied and streaked with fat at one spot near the apex; the valves were healthy. There was a small patch of atheroma in the first part of the aorta, but the coronary arteries were normal. The lungs were œdematous, but all the other organs were healthy.

The symptoms in this case appear a little difficult of explanation except upon the theory of disturbed cardiac innervation, for which, however, there was no apparent cause. The temporary lapses into unconsciousness and the attacks of tonic spasm appeared to be the result of cerebral anæmia.

Chancery-lane, W.C.

DYSTOCIA FROM RELATIVE SHORTNESS OF THE FUNIS.

BY JOHN A. LYCETT, M.D. ST. AND.,
SURGEON TO THE WOLVERAMPTON HOSPITAL FOR WOMEN.

A WOMAN, aged thirty-three years, the mother of two fine healthy girls, the younger three years old, was recently attended by me at full term. The labour was slower in progress compared with her previous confinements, the pains being of short duration and not strong. The presentation was first cranial or left occiput anterior. When the head was bearing upon the perineum evidence of the nature of the difficulty became manifest by great retraction between the pains, which were becoming shorter and less effectual, though not from exhaustion, as she continued cheerful with a good pulse. Pelvic examination showed no cause, there being ample space with yielding soft parts, and the nature of the presentation was further confirmed by feeling with ease the pinna of the left ear. Abdominal examination showed a single gestation with the placenta at the fundus, where the rotundity became much less defined during uterine action. Though during labour a firm bandage had been applied round the abdomen it became evident that nature, unaided, could not effect delivery, which had appeared so imminent for over an hour. Forceps were therefore used and the occiput carried round the symphysis without injury to the perineum; this was accompanied by hæmorrhage. The diagnosis was now verified by finding a strong, rather thick cord passing over the thorax round the back of the neck. The tension was so great that it was impossible to slip it either over the head or shoulders, so I divided it between forceps, as it was uncertain which was the fœtal end. The shoulders and arms were now freed, and a male child weighing over eleven pounds, and twenty inches in length, was delivered. As hæmorrhage continued rather free and the placenta could not be expelled by Crédé's method ergot was given, and the hand immediately introduced, when about a fifth part of the placenta was found attached at the fundus with a large clot. I regret that the length and strength of the cord were not ascertained, but it was about nineteen inches long, and as an average cord shown by the late Dr. Matthews Duncan[1] will bear a weight of eight pounds this evidently would not have broken under a weight of twelve pounds. Generally when the cord is too short the placenta under the tensile force of labour becomes detached from the uterus as in this case, but the cord has been known to tear from either the placental or umbilical site, and when weaker than normal snap through during labour, as related by Dr. Johnson.[2] It is not uncommon for the cord to encircle some part of the child, and less marked degrees of relative shortening may arise sufficient to retard delivery, even to partially detaching the placenta without being recognised. During an experience of nearly twenty-five years I have no note of labour being impeded from actual shortness, but have met with several where relative shortness has been a cause of dystocia. This, however, is the only occasion where the symptoms and physical conditions were sufficiently obvious to enable a diagnosis to be, with reason, inferred before delivery. The mother predicted a male child partly from the different character of the labour, and also from carrying it during the later months much higher than in the previous gestations.

Wolverhampton.

CASE OF TRANSPOSITION OF THE VISCERA, WITH A TRICŒLIAN HEART.

BY HENRY JELLETT, M.D., B.CH., B.A.O. DUB.,
ASSISTANT MASTER, ROTUNDA HOSPITAL, DUBLIN.

IN June, 1896, I was summoned to see a baby who had been just born in the Rotunda Hospital in an asphyxiated condition. When seen, the child was respiring feebly, the heart was weak and irregular, and the face and body were cyanosed. I commenced Schultze's method of artificial respiration, gave the child hot baths, and rubbed the lips and mouth with whisky. I felt for the heart in the usual manner—i.e., by pressing the fingers upwards under the ribs a little to the left of the middle line—but I was unable to feel its pulsations owing to the presence of what I at first took to be a greatly enlarged liver. I then palpated the abdomen on the right side to determine the size of the liver. Instead of finding it there as I expected, I was able to press my fingers upwards beneath the ribs, and to feel the pulsations of the heart to the right of the middle line. It was plain, then, that it was a case of transposition of at least the heart and liver. All attempts to revive the infant failed, and the child died in ten minutes. I made a post-mortem examination of the body the same day, and discovered that it was a case of complete transposition of the viscera. The normal position of the lungs, heart, liver, stomach, spleen, and intestines was reversed. The heart was almost twice the normal size, and when opened was found to have but three cavities—two auricles which opened into a common ventricle.

Many cases of partial transposition of the viscera have been recorded, but the number of cases in which complete transposition occurred is comparatively few. Two theories as to

its causation are suggested. Von Baer has found that in a few instances the embryo lies with its left side directed towards the yelk, whereas the right side is normally in this position. He considers this condition in all probability the cause of the transposition. Dr. Fraser, in a communication read before the Royal Academy of Medicine in Ireland (May 25th, 1894), thinks the transposition may be due to the subject having been one of twins which were developed from a single ovum and in which dichotomy was complete. He also exhibited a thoracopagus monster, in which the right-hand fœtus had complete transposition of the viscera.

ST. GEORGE'S HOSPITAL.

A CASE OF TUMOUR GROWING FROM THE BASILAR PROCESS OF THE OCCIPITAL BONE AND COMPRESSING THE MEDULLA AND PONS; NECROPSY; REMARKS.

(Under the care of Dr. H. D. ROLLESTON.)

THIS is a very interesting account of an unusual form of tumour of the base of the brain, which, growing from the bone, produced symptoms, which are carefully described, by pressure on the important parts at the base. "Tumours of the base of the brain[1] deserve special mention. They usually spring from the dura mater, sometimes from the bone. Sarcoma and carcinoma are most frequent; less common are psammoma, cholesteatoma, syphilitic gumma, enchondroma, fibroid growth, and hydatid cyst. The petrous portion of the temporal bone, or the dura mater over it, is the part from which growths most frequently spring. The neighbourhood of the sella Turcica is another common seat, and sometimes they originate in the posterior fossa, adjacent to the foramen magnum. They may spring from the bone in this part. They often attain a considerable size, even that of a hen's egg, and compress the superjacent brain." For the notes of this case we are indebted to Dr. W. Thomas, house physician.

A boy, aged seventeen years, was admitted into St. George's Hospital on Aug. 27th, 1896, complaining of seeing double when he looked to the left. He said that two months ago during very hot weather his speech became indistinct. He also suffered from severe pain in the top of his head. He was sick every morning, retching a good deal, but bringing up very little. This continued for three weeks. The sickness then ceased and his speech became clearer. The headache remained and he noticed that on looking to the left he saw double. He was a heavy-looking boy and took some little time to collect his thoughts on being asked questions. The right side of his face seemed to move less easily than the left, but as it never altered it may possibly have only been habitual and not connected with his disease. On asking him to put out his tongue it was noticed that it was pushed over to the left side. It was covered with a thick, creamy, yellow fur, and the left side felt flabby when pinched between the fingers. The movements of the eyes were perfect in all directions except the outward movement of the left eye. The left eye did not move outwards so quickly or so far as the right eye did inwards. There was some loss of power in the left external rectus. It was in performing this movement that diplopia resulted. The pupils were equal and reacted to light and accommodation. The fundi were normal. No evidence of paralysis of the sterno-mastoid or trapezius could be made out. The knee-jerks were normal, the left being slightly weaker than the right. Superficial reflexes were present, but sluggish. There was no ankle clonus. There was no loss of power in the arms and legs. The right grip was stronger than the left. He was able to walk perfectly and could turn round quickly without faltering. The heart and lungs were normal. The abdomen was slightly retracted, but otherwise normal. There was on marked wasting. The pulse was 110, regular, and fairly strong. The urine was clear, specific gravity 1020, no albumin or sugar. There was a deposit of phosphates on boiling. His bowels were most irregular, acting only with enemata. Eventually they were found to act better with German brandy and occasional enemata. The tongue did not clean after this, so its coat was thought to be due to imperfect mastication. On getting up in the morning he complained of giddiness and a feeling of nausea. After two or three days he became sick every morning and sometimes during the day. The headache continued, the pain being most intense in the occipital region. He was given quinine and iodide of potassium, but without any effect except slight coryza and an acne rash. On Sept. 25th he was given fifteen grains of sulphonal with ten grains of phenacetin twice a day. This relieved him completely of his headache, but kept him in a drowsy condition during the day in addition to making him sleep at night. It was found that giving him occasional doses at night kept him free from pain. This treatment was continued for seven weeks without producing any toxic effects. About a week after his admission it was noticed, after swallowing some milk, that he coughed and a portion of it regurgitated through his nose. At the same time his voice acquired a slight nasal intonation and his speech became somewhat thick. On examining the fauces the soft palate was seen to act sluggishly, the left side more so than the right. There was some response to a stroke with a pen-holder on the right side, but hardly any at all on the left. He, however, continued to take his food well for some time after this without any further regurgitation taking place. The giddiness and retching became more marked on rising. His gait became unsteady and he complained of great weakness in the legs. He was, therefore, kept entirely to his bed. After this (Sept. 14th) his condition gradually deteriorated. The paralysis of the left external rectus became more and more marked and finally complete. Slight swelling and haziness of the optic discs were noticed on Nov. 1st. The tongue was still protruded to the left. The paralysis of the soft palate gradually became complete, with constant regurgitation of liquids through the nose. On this account he was fed through a tube passed into the stomach, as it was thought food pneumonia would otherwise inevitably follow. After withdrawing the tube, however, he used to vomit and so he incurred the same risk as before. The nasal intonation increased, the speech became thick, and the words blurred so that it became impossible to understand him. The saliva ran from his mouth and soaked his pillow. He wasted considerably. The knee-jerks entirely disappeared, but the plantar reflexes remained. No anæsthesia on the left side of the face or deafness were ever noticed. The heart's action continued regular, but gradually quickened from 84 to 120 beats per minute, at which rate it remained for some time before his death. The lungs remained quite free till about a week before his death, when bubbling râles were heard at the bases. These increased in number, and were finally heard all over the chest. Cheyne Stokes breathing was never observed. The temperature throughout the course of the disease was inclined to be sub-normal, varying from 96° to 99°F. On Nov. 13th, in the afternoon, after being fed through the tube, he vomited a considerable quantity of fluid. Some of this got into the air-passages, for he became extremely cyanosed and short of breath. He was put on his side and given oxygen to inhale, when some slight improvement followed. He was then fed entirely with nutrient enemata. The improvement, however, was only temporary, for both the pulse and respiration quickened, the temperature rose to 102°, and at 1 A.M. on the 14th he died.

Necropsy.—At the post-mortem examination the bones of the cranial vault were found to be considerably thinned in places. The brain weighed 50 oz. and the convolutions on both sides were flattened; this was due to the distension of the ventricles with clear cerebro-spinal fluid. There was a lobulated tumour as large as a Tangerine orange growing from the anterior surface of the basilar process about the junction of the basi-occipital and basi-sphenoid bones. A longitudinal section of the bone showed that the tumour was sub-periosteal and that it did not expand the basilar process. The growth was covered over by the dura mater and had not perforated it in any place. The tumour was white on section and grated under the knife; it presented the appearance of a cartilaginous tumour undergoing calcification; microscopically it was a chondrifying and calcifying sarcoma.

[1] Gowers: Diseases of the Nervous System, second edition, p. 499.

Hosted by Google

The pituitary body and fossa were quite natural. The basi-sphenoid and basi-occipital bones were firmly united by bone. The tumour indented the pons and the medulla and markedly flattened them on the left side. The fifth nerve on the left side was flattened; the left sixth nerve was pressed upon; while the seventh and eighth nerves on that side were in immediate contact with the tumour. The glosso-pharyngeal, vagus, spinal accessory, and hypoglossal on this side were surrounded by an extension of the growth, which passed down through the left jugular fossa to get behind the upper part of the pharynx. The growth did not press on the right side of the medulla or pons. There were retinal hæmorrhages on both fundi and obscuring of the disc. There was a persistent thymus, which, however, seemed to be atrophying, as shown by microscopic examination. The right lung showed broncho-pneumonia due to the entrance of food. The other organs were healthy.

Remarks by Dr. ROLLESTON.—The points of interest are in connexion with the diagnosis, treatment, and the origin of the tumour in this case. During life the diagnosis was a tumour *in* the upper part of the medulla, whereas the tumour, as has been seen, was *outside* the medulla. This error might have been obviated by bearing in mind Dr. Gowers's statement that in tumours arising from the posterior fossa of the skull the sixth nerve is paralysed without the conjugate internal rectus, which suffers with it in disease of the centre.[2] The nerves affected clinically were the sixth, tenth, eleventh, and twelfth, and the tumour was therefore thought to be in the upper part of the medulla, involving the fibres of the sixth at their exit and not affecting the nucleus of the nerve, for in that case the seventh nerve would have been affected as well. This diagnosis was made soon after admission, when there were two other factors which in my mind strengthened the localisation: they were (*a*) the absence of optic neuritis and (*b*) the sub-normal temperature. Optic neuritis may be absent in cases where the tumour is situated in the medulla. Dr. J. M. Martin has most kindly communicated to me the following figures bearing on this point. In 41 cases of tumour of the pons and medulla there was no optic neuritis in 14, or 34 per cent., while in 9 of these 41 cases in which the tumour was situated either low down in the pons or in the medulla, optic neuritis was absent in 5 A tumour irritating the meninges would be more likely to give rise to optic neuritis, and, as has been seen, papillitis did occur two weeks before death in this case. With regard to the sub-normal temperature, I had heard of two or three cases of tumour in the medulla in which this feature was noticed, and its presence in this case seemed to confirm the diagnosis.

With regard to other points the clinical symptoms were less widely spread than the lesions found post mortem rendered probable; thus there was no definite facial paralysis or deafness, and though there was headache it was not localised to the fifth nerve on the left side, and there was no anæsthesia on that side of the face. Pressure on the pons eventually gave rise to loss of power in the legs, but there were no convulsions; the loss of knee-jerk which developed was probably due to the cerebellum being compressed under the tentorium by the upward growth of the tumour. As regards treatment, iodide of potassium was tried on admission, but without any result, and as there was no evidence or history of any specific taint it was, after a fair trial, abandoned. A tumour that appeared to be in the medulla was in too dangerous propinquity to the vagus and the all-important vital centres to encourage any idea of operative interference, and we had therefore to be content with relieving pain and sleeplessness, which the combination of ten grains of phenacetin and fifteen grains of sulphonal very successfully achieved. The tumour during life was, from the absence of any sign of syphilis, the failure of iodide of potassium to relieve the symptoms, and from the age of the patient, thought to be either gliomatous or tuberculous. As shown at the post-mortem examination, it was a chondrifying and calcifying sarcoma growing from the surface of the junction of the basi-sphenoid and basi-occipital. These two bones normally join at about the age of twenty-one years; in this case they were firmly united by bone, no trace of the junction being visible. This premature union was perhaps associated with the riotous proliferation which gave rise to the sarcoma. It is possible that this growth arose from some relics of the primative parachordal cartilages, but as it did not expand the bone and was sub-periosteal and not endosteal there is not much to support this suggestion. There were no signs of cretinism, but it is interesting to note that together with this premature ossification between the basi-sphenoid and basi-occipital there was a persistent thymus, which, however, showed signs of atrophying. A persistent thymus is found, according to Marie,[3] almost constantly in cretinism (infantile myxœdema). Possibly this case was one in which cretinism remained entirely latent, although there were some anatomical evidences of it.

ENGLISH MISSION HOSPITAL, JERUSALEM.

A CASE OF LARGE CONGENITAL SCROTAL HERNIA; RADICAL CURE; RECOVERY.

(Under the care of Mr. ERNEST W. GURNEY MASTERMAN.)

CASES of radical cure of all kinds of hernia are now so common that only those of special interest claim notice in "the Mirror." The reason for recording the following case is the very large size of the hernia. Perhaps, also, the fact of its being of the congenital variety may add to its interest.

A Moslem boy, stated to be twelve years of age, but, if so, very ill developed, was admitted to the English Mission Hospital, Jerusalem, on April 20th, 1894, with a large right inguinal hernia, which his mother stated he had had all his life. It was quite irreducible and had lately increased in size. The great weight of the mass in the scrotum made the boy's life a burden, and both he and his mother were most anxious for any treatment which would end this misery. When admitted his general condition was fairly good for a native. There was no other sign of disease. The bowels acted fairly regularly and there was no vomiting. The note of the local condition, taken at the time, was as follows: "Passing down the right inguinal canal and distending the scrotum to the size of two fists, when held together, is a large hernia. It can on manipulation be very slightly reduced, and when the state of extreme distension is removed the contents appear to be partly omentum and partly intestine. A distinct circular hard band feels to be undoubtedly omentum." (At the operation it proved to be a loop of altered small intestine). On the 24th the patient was put under chloroform and an attempt at reduction was made without success. On May 1st, with the assistance of Dr. P. D'E. Wheeler, Mr. Masterman performed the following operation. The patient, having been previously prepared by a purge and enema, was put under chloroform. After thorough antiseptic cleansing of the parts an incision was made about four and a half inches long from about half an inch above the site of the external abdominal ring to nearly the bottom of the scrotum. The peritoneal sac was opened on a director and the contents were found to be six coils of small intestine, normal in appearance except one coil, which was much reduced in calibre, and was empty and hard. Behind these lay a large mass of large intestine, including the cæcum with the vermiform appendix, the ascending and the transverse colon. To this last was attached the great omentum, the whole of which was in the hernial sac. The small intestine was soon reduced, but the mass of large intestine was so matted together that its reduction was a matter of great difficulty. The appendices epiploicæ were large and contained much fat. As the omentum was normal and not abnormally drawn into bands it was not thought advisable to remove any of it. After twice carefully slightly enlarging the incision upwards the whole mass was at length reduced. During these manipulations the intestines were as far as possible kept warm by means of sponges wrung out in warm carbolic lotion. After the reduction, the neck of the sac (which was large enough to admit three fingers together) was closed in the following way: Three salmon-gut sutures were passed transfixing the sac, each one deeper—i.e., posterior to—the others, and all were knotted above one another above the neck. Then a stout silk ligature was passed still deeper than—i.e., posterior to—all these, and in its passage across the inside of the neck included part of the floor—i.e., posterior surface—of the neck. When this was tightened up it was found that there was a small space left large enough to admit the tip of the little finger. A further suture was

Hosted by Google

then passed deeply completely round the sac outside its coats, and this being tightened the sac was closed. A special effort was made to avoid including the spermatic cord in these sutures, even although the testis on that side was very ill developed, being much smaller than the one on the other side. The sac being closed, a considerable portion of the tunica vaginalis was dissected away, but considering the state of the testis it did not seem to be worth while spending more time in suturing together a new tunica vaginalis testis. A large piece of the scrotum, 4½ in. by 2 in., was then removed. The long wound was then carefully sewed up with salmon-gut sutures and a small drainage-tube was inserted at its lowest point. On the 2nd the patient had had a fair night, there had been no vomiting after the chloroform, and the temperature at 6 A.M. was 100 3° F. and at 6 P.M. 103°. He was fed on nutrient enemata. Sips of hot water only were given by the mouth. On the 3rd he was doing well. Nourishment as above was given. A little hot milk by the mouth, a teaspoonful at a time, was added. The bowels acted naturally; there was no abdominal tenderness. The temperature at 6 A.M. was 102 4°, and at 6 P.M. 104°. The wound was dressed; two stitches were removed; there was slight suppuration at the upper end and a boracic fomentation was applied to that part. On the 4th there was free discharge, the remaining stitches were removed, and the temperature was 100·6°. After this the temperature became normal and ordinary feeding was resumed. There was a somewhat free discharge of pus from the whole length of the wound; but on July 10th the patient left the hospital with a very firm consolidated scar in the site of the wound and the scrotum only slightly larger than normal.

Remarks by Mr. MASTERMAN.—From the point of view of antiseptic surgery this free suppuration might be regarded as a failure, though, so far as I have seen, it is very common in all hernia operations of any size involving scrotal tissues; but practically it led to the formation of a very much more hopeful and satisfactory scar than could have occurred had all closed by "first intention." I have made every endeavour to see my patient again of late, but he cannot be traced; yet the fact that he has neither come to me nor to the English practitioner at Nablous, where he lives, makes it almost certain he is going on satisfactorily without recurrence.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Parasite of Malarial Fevers at Sierra Leone.—Pulsating Empyema.

A MEETING of this society was held on March 23rd, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Surgeon-Captain C. W. DUGGAN read a paper on the Parasite of the Malarial Fevers at Sierra Leone. He described the symptoms of the severe malarial fevers which prevail at Sierra Leone, and gave the results of his observations on the parasite of malaria which is associated with these fevers, from which both Europeans and natives suffer. During two years' residence there he examined blood from the finger in nearly 400 cases and made special study of 50 cases. Eleven of these cases were given in some detail in the paper. His description of the symptoms which usher in and last during the attack did not differ materially from that given by previous observers. In all the cases he found parasites in the blood from the finger. The form in which they were seen was as a very minute ring-shaped body, which in a later stage slightly enlarged, and contained a few very minute grains of pigment. A more advanced stage than this was not observed in the freshly drawn peripheral blood, with one or two exceptions. In blood taken from the surface of the brain in a fatal case he found sporulating forms. The parasite is very small, and even in the sporulating stage only takes up about a third of the red corpuscles. He counted five spores in one parasite. In the majority of cases, after some days' fever, the crescent forms of the parasite were observed, and he described various stages in its development. In one case only did he observe appearances in the parasite which could be interpreted as being possibly due to spore formation. In all the cases observed by him the tertian parasite was observed once only. This occurred in a man who had suffered from malarial fever two years previously in the West Indies. The quartan parasite was never observed. All the appearances observed were analogous to similar appearances described by Marchiafava as being found in the summer-autumn fevers of Rome, and morphologically Surgeon-Captain Duggan was not able to detect any difference between Marchiafava's parasite and that of Sierra Leone. The crescent body in shape and size resembled that described by Laveran and the Italian authors. In dried and stained preparations of the small parasite in the finger blood a deeply stained nucleolar body could sometimes be observed at one point in the periphery; at other times in the centre of the parasite surrounded by an unstained zone, whilst the periphery stained; sometimes two such nucleolar bodies could be observed. In the stained preparations the very fine pigment was observed on the periphery of the parasite.—Dr. THIN remarked on the importance of a microscopic examination, and mentioned a case in which there was no fever, but in which by careful searching Surgeon-Captain Duggan established the diagnosis by demonstrating the malarial parasite. The fevers on the west coast of Africa were extremely fatal as compared with those in the south of Europe, and this appeared to be due to a plurality of parasites. As illustrating the danger to Europeans he mentioned an instance in which four out of five artisans died from fever almost immediately after arrival in the country. One of them was attacked on the second day, showing an unusually short period of incubation. Death occurred on the fourth day. The regular administration of quinine had a most remarkable protective effect.—Dr. MANSON drew attention to the previous work of Plehn in the Cameroons, which pointed in the same direction. Microscopic examination was of the utmost importance for purposes of diagnosis, as many of the cases now known to be instances of severe malaria would formerly have been returned as cases of sunstroke. He regarded the practice in the army of discharging men from hospital after three days' treatment as quite inadequate, as observations showed that the parasite recurred in the blood at the end of a week. Patients should be retained in hospital for two or three weeks until the parasite had entirely disappeared from the blood, and if the presence of the parasites was persistent the patient should be deported from the country. He was surprised that reference was only made to the crescentic forms, as the flagellated forms could easily be produced by placing the cover-glass with the film of blood in a damp cell made with a piece of wet blotting-paper. With reference to transmission of the parasites by means of mosquitoes, he pointed out that the transference was not direct, as the mosquito did not suck blood more than once. He believed that this insect was the host in which the parasite developed, and he had specimens demonstrating the presence of the flagellated form of the parasite in its stomach.—Surgeon-Captain DUGGAN, in reply, said that he had no doubt that flagellated forms would have been obtained in his cases by keeping, but he did not see any in freshly drawn specimens. He could hardly regard the mosquitoes as essential for the conveyance of the parasites, as they were not numerous in the fever-stricken districts on the west coast, and then only appeared for a short period in the year.

Dr. SAMUEL WEST read a paper on Pulsating Empyema. Distinct pulsation in empyema was of two kinds: (1) A general shock, usually communicated to a considerable area of the chest wall—intra-pleural pulsation, as it has been called; and (2) expansile pulsation localised in an external tumour—extra-pleural pulsation. In either case it is usually on the left side, synchronous with the heart, and almost invariably systolic in time. It is most frequent in males and in adult life, but may occur in either sex or at any age. Similar pulsation has been described with serous effusion and pyo-pneumothorax. Intra-pleural pulsation is usually palpable only—and rarely visible—over a considerable part of the side. When localised to the upper intercostal space it is probably like the fluctuation of ascites, and due to a surface wave, and is met with only where the effusion is large, the diagnosis presenting no difficulty. If felt near the sternum or near the heart the question of aneurysm might arise. Pulsating pneumonia and intra-thoracic growth have been mentioned as causing difficulty in diagnosis, but both these

Hosted by Google

conditions are very rare. Extra-pleural pulsation is met with in empyema only when pointing. Its seat is usually near the heart. There may even be two or more external tumours, all of which pulsate. Such pulsating empyemata have been met with in strange places—e.g., the loin. The diagnosis is but rarely a matter of difficulty. It is with aneurysm that these cases are most likely to be confused. In one case the pulsating tumour was in the third left intercostal space, and after being regarded and treated as an aneurysm for three years burst and disappeared. Localised empyemata near the heart do not necessarily pulsate, however, nor need aneurysms do so. The difficulties of diagnosis are greater between a local abscess in the chest wall which pulsates and an aneurysm than between an aneurysm and a pulsating empyema. Puncture with a fine needle could do no harm even in an aneurysm and would at once settle the diagnosis. There are three different kinds of pulsation in empyema, and the same explanation will not fit all :—1. The general shock with large effusions, probably the same as that occasionally felt through a solid growth or even a massive pneumonia, and is a shock rather than a pulsation. 2. The wave-like pulsation, often limited to one or two of the upper intercostal spaces in front, probably a surface wave like the so-called fluctuation in ascites. 3. The distensile pulsation, like that obtained in a large abscess, and for this it is necessary that the fluid should be contained within more or less resistent walls and be under some tension, and usually thickening and rigidity of the lung and mediastinum are found post mortem in such cases. Pulsating empyemata are usually said to be fatal, and this statement is approximately true when the pulsation is distensile. The prognosis is so bad, not because the empyema pulsates, but because the peculiar conditions requisite for pulsation—viz., the fixation of the heart and the changes in the mediastinum and lungs—are such as prevent recovery. Of the other cases the majority recover when treated in the usual way.

MEDICAL SOCIETY OF LONDON.

Intestinal Anastomosis.—Senile Decay.

A MEETING of this society was held on March 22nd, the President, Mr. REGINALD HARRISON, being in the chair.

Mr. HARRISON CRIPPS read a paper on three cases of Intestinal Anastomosis. The first was one of end-to-end anastomosis of ileum to ileum in a young woman in whom obstruction followed abdominal section for hysterectomy. A temporary enterotomy was performed, and ten weeks later the bowel was divided just below the obstructed portion and again just above the enterotomy opening, the ends being carefully sutured. She recovered, and now, three years after the operation, was in excellent health and well nourished. The second case occurred in a man, fifty-five years of age, who was operated on at his urgent request for a tumour which was found to involve the transverse colon, the omentum, and a coil of the ileum. The growth was removed and the large and small intestines were sutured, but death occurred on the fifth day, probably from septic peritonitis. The third case was that of a woman, twenty-three years of age, suffering from intussusception. Her condition precluded any prolonged operation, and a temporary enterectomy was performed as low down in the ileum as possible. On the eighth day the opening was blocked by a foreign body, which proved to be the intussusceptum which had sloughed. After a time some of the motions passed by the rectum, but the bulk escaped through the artificial opening, and if this was closed by a plug the abdomen became distended and symptoms of obstruction recurred. The patient became greatly emaciated, and it was urgently necessary to establish free communication with the large intestine. A firm plug was therefore placed temporarily in the existing opening, in order that the skin might be thoroughly cleansed, and the abdomen was then re-opened nearer the middle line, without disturbing the adhesions of the existing opening, and a lateral anastomosis was made between the commencement of the ascending colon and the lowest part of the ileum available. The fact that the intestines were no longer distended greatly facilitated the operation. The patient was now in good health, but there was a small fistulous tract at the site of the original enterotomy wound. Mr. Cripps spoke strongly in favour of trusting to careful stitching, and said that he was more than ever disposed to regard bobbins and buttons as incomparably inferior and as the cause of otherwise avoidable deaths.—Mr. LOCKWOOD said that he had seen double enterectomy performed in one case, in which death occurred not from shock but from leakage at both lines of junction. The most favourable site for operation was the small intestine, because the contents there were fluid and the movements of the gut were less forcible. He questioned whether advantage was gained by removal of a wedge of mesentery. With regard to the method of uniting the bowel, he preferred end-to-end suture to lateral anastomosis. He agreed that it was advisable where possible to relieve the distension by a preliminary operation, but he quoted cases to show that distension need not prevent the surgeon from operating where the symptoms were urgent. The condition of the patient was of great importance, as he believed that intestinal paralysis was much less likely to occur in persons who were strong and vigorous.—Mr. MARMADUKE SHEILD asked for details of the method adopted by Mr. Cripps to obtain anastomosis by lateral approximation. He himself was in favour of dispensing with any apparatus and trusting to the fingers and silk sutures.—Mr. L. A. BIDWELL asked for details of the method of end-to-end anastomosis. In employing Maunsell's method he had found that supplementary Lembert's sutures were required. He had seen one of his cases of end-to-end anastomosis two and a half years after operation, and there was no sign of stenosis.—Mr. G. WALLIS remarked that if a large wedge of mesentery was removed there was apt to be gangrene of the gut.—Mr. CRIPPS, in reply, could not agree that there was any greater risk or difficulty in the long run in operating on the large as compared with the small intestine. He had long discarded Maunsell's method as tedious. For end-to-end suturing he employed Lembert's sutures, inserting the needle a quarter of an inch from the cut end, and taking in an eighth of an inch of peritoneum and muscular coat only, ten or twelve sutures being inserted to the inch. In performing lateral anastomosis he first passed sutures to unite the coils of intestine near their mesenteric attachments ; these sutures were then drawn tight to seal off the posterior line of attachment. Sutures were next drawn through the anterior line of attachment, but they were not tightened until a longitudinal incision had been made in both coils of intestine. He never used Murphy's buttons.

Dr. T. D. SAVILL read a paper on Senile Decay, its Causes and Treatment. The paper was based chiefly on 409 cases of death in persons of sixty years of age and upwards observed during the seven years that Dr. Savill was medical superintendent of the Paddington Infirmary, the inquiry having been begun in 1887. The first part of the paper dealt with the normal and abnormal symptoms of old age, among the former being weakness, nervous symptoms, the senile heart, the senile pulse, and various external signs, among the latter being "senile vertigo," "senile epilepsy," and, lastly, conditions attended with high arterial tension. These conditions he considered dependent upon certain changes occurring chiefly and uniformly in the muscular coats of the arteries, and he referred to communications already made by him on the subject showing this condition of "hypermyotrophy" to be independent of renal disease. Dr. Savill next considered the characteristics of disease as it occurred in aged persons. Pneumonia took the leading position as a cause of death, with 17 per cent. ; then cancer, 15 5 per cent. ; then bronchitis, 11 per cent. ; then "senile decay," 9 per cent. ; then contracted granular kidney, 6 per cent. ; and pulmonary tuberculosis, 5·5 per cent. The figures showed that tubercle was not so rare in the aged as was generally believed. He concluded by pointing out the importance of the early recognition of high arterial tension and of its treatment by appropriate remedies. Nitro-glycerine was of great value in the treatment of the pathological degree of the arterial change—a point supporting his contention that it was the muscular tissue which was at fault. A large number of photographs, pulse-tracings, and microscopic specimens were shown.—Dr. CLIFFORD ALLBUTT said that he was not prepared to admit that the changes described by Dr. Savill were physiological and incidental to old age. In many old people no change could be made out in the radial artery, and the blood-pressure was low. But he thought that there was a malady common in old age, of which some of Dr. Savill's cases were instances, in which the advance of years was accompanied by increase of blood-pressure. Some of the subjects were pale and sallow, others were florid. He had

Hosted by Google

described these cases clinically under the title "senile plethora." There was usually a train of nervous symptoms, melancholia, insomnia, vertigo, bewilderment, syncope, and the like. The cause of this increase of tension was very difficult to determine. The urine showed no alteration, the urea and uric acid when estimated being found to be present in normal amount. There was usually some enlargement of the heart, so far as could be estimated by percussion. The ventricle was not emptied at each systole, and tended to become dilated and afterwards hypertrophied.

CLINICAL SOCIETY OF LONDON.

Thrombosis of the Veins of Galen after Scarlet Fever.—Sclerema Neonatorum. — Peripheral Hyperostosis. — Urobilinuria following the administration of Trional.

A MEETING of this society was held on March 12th, the President, Dr. BUZZARD, being in the chair.

Dr. E. W. GOODALL related a case of Scarlet Fever in which death was due to spontaneous thrombosis of the veins of Galen. The patient was a girl, eight years of age, who was admitted into the Eastern Fever Hospital with a moderately severe attack of scarlet fever. On the evening of the eleventh day, when apparently convalescent, she was seized with a succession of general convulsions, which after a few hours gave rise to more or less general rigidity and gradually deepening coma. There was pyrexia, the temperature rising shortly before death to 107·4° F. The pulse was very frequent. There was no optic neuritis and the urine was free from albumin during the whole of the illness. At the necropsy there was ante-mortem clot in the veins of Galen and in the straight sinus. The clot was hardly if at all adherent. Both choroid plexuses were covered with a thick layer of recent lymph. The optic thalami were in a condition of red softening, the left being almost diffluent. Beyond slight ulceration of the tonsils there was no other lesion. There was no middle-ear disease. The case was brought forward on account of its rarity, as when spontaneous thrombosis occurs after a specific fever it is usually located in the heart or one of the vessels of the lower extremities. A case similar to this was brought before the society in 1896 by Dr. Lee Dickinson, but in that case no cause for the thrombosis could be found.—Dr. COUPLAND related a case that he had seen with Dr. F. P. Wightwick, in which a young woman, who, when convalescent from an attack of measles seventeen days after the onset, became strange in her manner and passed urine and fæces under her. Next day she had intense headache and became semi-comatose, the left arm was flexed and a little rigid, but the other limbs were flaccid. The knee-jerks could not be obtained. There was albumin in the urine, and her temperature, which was 104° when first seen, rose to 108° before death. Thrombosis of the sinuses was diagnosed, and at the necropsy ante-mortem clot was found in the straight sinus. There was red softening of the optic thalami and a small area in the crus. There were no convulsions during the illness.—Dr. LEE DICKINSON said that in the majority of cases the patients were chlorotic. A few had occurred in association with pneumonia and with the puerperium. They are primarily dependent on the condition of the blood and not to phlebitis. The recent work of Wright and others led him to hope that they might ultimately be able not only to recognise undue coagulability of the blood, but to remedy it and prevent thrombosis.—Dr. GOODALL, in reply, said that his patient was not particularly anæmic. The case had run an ordinary course, and no examination of the blood had been made.

Dr. GARROD related a case of Sclerema Neonatorum in a male infant, the child of healthy parents, who were not in specially bad circumstances. Three or four days after birth patches of induration of a purple colour were noticed on the buttocks. When first seen, at the age of seven weeks, the child was well nourished and showed no constitutional symptoms, and there was no depression of temperature, which was taken on seventeen occasions, and varied from 100° F. to normal. Areas of sclerematous induration were situated over the buttocks, thighs, back, and deltoid regions, and there were a few outlying islets in other situations. The skin over the buttocks had a pink tint. The induration was massive, and the legs could not be extended at the hips. There was nowhere any pitting on pressure. The distribution of the sclerema was very symmetrical. The edges were map-like and well defined. The urine was pale, clear, and contained no albumin. The induration gradually cleared up, and recovery was complete in about five months. The treatment adopted was inunction with mercurial ointment, and later with cod-liver oil. In this case, as in one previously recorded by Dr. Garrod, the disease had evidently passed through its period of activity before the child was first seen, and this explained the absence of constitutional symptoms. In favourable cases the initial fall of temperature may be comparatively slight. The vigorous condition of the child, the absence of privations, and the fact that it was born in summer, were all factors tending to a favourable termination.

Mr. LOCKWOOD read a paper, and Dr. LEWIS JONES exhibited skiagrams, describing the case of a girl, ten years of age, suffering from Peripheral Hyperostosis, which was considered in connexion with pulmonary hypertrophic osteo-arthropathy. The hands and forearms, also the feet and legs, were much enlarged. The enlargement was mainly due to a thickening of the diaphysis of the bones of the leg. The soft parts may have been altered, the legs being œdematous. The girl had a sharp angular curvature of the spine in the dorsal region, but no abscess. The lungs were catarrhal at the base, and dulness at the apex indicated tubercle. Both the upper and lower extremities were enlarged. The fingers were clubbed with flat and spade-like ends. The phalanges and metacarpal bones were much thickened at the thin part of their shafts. The ends and joints seemed quite normal. The ulna and radius were also thickened. The legs were œdematous, but the lower end of the tibia and fibula and the bones of the foot and knee were much thicker than usual. The photographs showed an actual hyperostosis. The various bony thickenings seemed quite painless and without evidence of inflammation. There was impaired resonance and crepitations at the apices of the lungs. The absence of any joint affection seemed to separate this case from others of so-called pulmonary hypertrophic osteo-arthropathy. Thickening could hardly be due to periostitis. It was analogous, he thought, to the thickening on the concavity of the shaft of the bone sometimes seen in rickets.—Mr. MAKINS had seen a somewhat similar case in a girl aged twelve years, who had a dorsal curvature and big hands and feet resembling those in acromegaly. In his case, however, the skiagraphs did not show any change in the bones. He thought that the change in the phalanges resembled that in intra-uterine rickets.—The PRESIDENT asked if there had been any special treatment which accounted for the improvement. He thought that the case ought to be classed with hypertrophic pulmonary osteo-arthropathy rather than with acromegaly. Although the bones of the hand were thickened, the hand as a whole was not increased in width as in acromegaly, and the spinal curvature was lower than was usual in that complaint. There was hyperextension of the distal phalanges, as in Marie's description, but there did not appear to be the usual changes in the nails.—Dr. KINGSTON FOWLER drew attention to the clubbing of the fingers and asked if there were any signs of bronchiectasis. He referred to a case in which there were enlargements of the metacarpo-phalangeal joints and great clubbing of the fingers, in which at the necropsy the mischief proved to be extra-articular, and in which the clubbing entirely disappeared after death.—Mr. LOCKWOOD, in reply, said that there had been changes in the nails, but that they had disappeared as the child's health improved. He attributed the improvement to her removal from miserable surroundings and to good food and nursing. As the joints did not appear to be implicated in this case he preferred to call it "hyperostosis" rather than osteo-arthropathy.

Dr. ROLLESTON showed a case in which Excessive Urobilinuria followed and apparently depended on the Administration of Trional. The patient was a woman, aged fifty-seven years, who for two years had suffered from dropsy, "jaundice," and progressive shortness of breath. On admission she had a dilated heart, slight œdema, and a dirty yellow skin. There were purpuric patches on the thorax and abdomen. The urine was highly coloured, but contained no bile, nor was there any albumin. On the evenings of Nov. 2nd, 7th, and 9th twenty-grain doses of trional were given. On Nov. 9th the urine was of a deep orange colour, and as the possibility of hæmato-porphyrinuria due to trional suggested itself the administration of the drug was stopped. Dr. Buckmaster examined the urine spectroscopically, and found no trace of hæmato-porphyrin, while urobilin was present in excess, as shown by the

Hosted by Google

fact that after dilution a well-marked band of urobilin was seen. The urine remained of this peculiar colour, though gradually diminishing in tint, until death on Nov. 17th. On Nov. 13th the temperature began to go up and delirium set in, which lasted until death from exhaustion. At the necropsy there was a localised empyema beween the lobes of the right lung, a dilated heart, and a "nutmeg" liver, which was not cirrhotic. It appeared probable that the patient had for some time been subject to urobilin jaundice, the source for excessive urobilin being the purpuric patches and the "nutmeg" liver, and that the trional brought about an increase in the urobilinuria. Urobilin and hæmato-porphyrin were closely allied, while sulphonal and trional resembled each other both chemically and physiologically. Sulphonal was known to give rise to hæmato-porphyrinuria. It seemed reasonable to believe that trional would give rise to excessive urobilinuria and that it would be specially liable to do so when there was excessive chronic venous congestion of the liver.—Dr. A. E. GARROD thought that hæmato-porphyrinuria did not necessarily imply excessive hæmolysis. In cases of profuse hæmato-porphyrinuria after sulphonal, examination of the blood did not show any active hæmolysis, but appeared to be due to an alteration of bilirubin by a special intestinal organism. Urobilin, on the other hand, was associated with increased hæmolysis and was hence increased in pernicious anæmia, in which hæmato-porphyrin was only present in the normal trace. It was also present in increased amount in cases of "nutmeg liver."

HARVEIAN SOCIETY OF LONDON.

Some Common Troubles following upon Childbirth.

A MEETING of this society was held on March 18th, Dr. MILSOM being in the chair.

Dr. BOXALL read a paper entitled Some Common Troubles following upon Childbirth. The chief facts relating to the mortality from puerperal fever were fully stated as statistics and illustrated by means of charts. Puerperal fever had not diminished in the past fifty years, but rather increased, especially in the provinces. In the practice of the General Lying-in Hospital during the "antiseptic period" (1879–1896) the mortality had been greatly diminished, and in all cases where the patient had been under hospital treatment throughout, not only had the mortality been diminished, but septicæmia had been eliminated and the death-rate had been lessened below that of private practice. Similarly satisfactory results had been obtained at other lying-in hospitals at home and abroad. Stress was laid on the superiority of perchloride of mercury solution as an antiseptic and on the details of its use. Dr. Boxall had found numerous cases of subinvolution, retroversion, laceration of the cervix, &c., in patients leaving the lying-in hospital, conditions requiring treatment being found in 56 out of 200 patients examined. He therefore recommended the routine examination of all patients before attendance ceased.

Dr. CULLINGWORTH bore testimony to the great value of the statistics collected by Dr. Boxall and also to the value of antiseptics, and dwelt on the results that had led to the discontinuance of "salufer" as an antiseptic.

Dr. MORTON called attention to the soloids of the biniodide introduced by Dr. Leith Napier. They were efficient, but more hygroscopic than the perchloride. He regretted that a longer trial had not been made of "salufer" in 1888.

Mr. HAZEL asked for particulars as to the technique of the process. Does the patient lie on her side or on her back? He mentioned the case of a patient under his care who was given the injection by the nurse whilst lying on her left side, and that she was caused so much local irritation and general disturbance thereby that she said she would rather die than have the injection again in this way. Did Dr. Boxall use a straight or curved tube; and did he prefer the tube to be of glass, gum-elastic, or celluloid?

The PRESIDENT observed that Dr. Boxall had made no reference to zymotic diseases in connexion with the subject. He would have liked to hear something about the effect of influenza, for he had seen two cases where the poison was very virulent, and in both instances proved fatal.

Dr. BOXALL, in reply, said that the douche was indicated before, during, and after labour. It was to be given into the vagina and not directly into the uterus, though some of the lotion entered the uterus, and should be squeezed out after douching. The dorsal position should be maintained throughout.

BRITISH GYNÆCOLOGICAL SOCIETY.

The Treatment of Inoperable Carcinoma.

A MEETING of this society was held on March 11th, Mr. MAYO ROBSON, President, being in the chair.

Mr. ARMSTRONG (Buxton) said that he had been asked to read a short paper on Dr. Beatson's Method of Treatment of Inoperable Carcinoma, but he was relieved of this duty by the presence among them of Dr. Beatson himself, who had come on the invitation of the council.

Dr. BEATSON (Glasgow), after acknowledging the invitation which he had received from the council through Mr. Armstrong, said that in his first case the mamma, axillary glands, and part of the pectoral muscle had been removed and found to be cancerous. Three months later the disease recurred, and further operation was impossible. Thyroid feeding was carried to the extent of producing a physiological effect, but in vain. The ovaries and tubes were then removed and the thyroid feeding again pushed. In little more than two months the patient had much improved; in five months the cancerous tissue had become yellow and fatty; and in six months it had gone. Now, at the end of twenty-one months, the tissues were sound and the woman was in good health. The case seemed to him to throw some light on the subject of carcinoma. He wished to specially consider three points—(*a*) the possible mode of origin of the cancer cells; (*b*) the relation of the cancer cells to surrounding tissues; and (*c*) the exciting cause of the cell-proliferation. (*a*) Did the cancer cells come from the normal epithelium of the part or had they an independent origin? The current view was that they arose from a transformation of the normal cells. But another idea was suggested by secondary growths. For instance, in the case of cancer of the liver secondary to a breast tumour they found that the breast-cells had become transplanted in the liver, whilst there was no proliferation of the liver cells themselves. Now if the liver growth had arisen from the proliferation of a cell implanted there, why might not such a process have been at work in the first place? (*b*) In a fast-growing carcinoma no bloodvessels were found; therefore, the growth must be nourished by surrounding lymph and neighbouring cells; from this he concluded that carcinoma cells must live on their neighbours. As some tissues formed better pabulum than others, the fact that some tissues were very resistant to cancer was thus explained. At the growing margin of a cancer the degenerate tissue cells testified to the parasitic action of the tumour. At the centre of the tumour, where no nourishing cells were present, the cancer cells tended to break down with a fatty, hyaline, or mucoid degeneration. (*c*). Three explanations had been given as to the exciting cause of the cell-proliferation. First, there was the recent parasite theory, which he regarded as not proven. Secondly, Cohnheim's theory was that it was due to the inclusion of epithelial cells. A third explanation was based on Goodsir's paper on Nutritive Centres, in which it was suggested that every organ had a nutritive centre in the shape of a few cells which normally disappear after they have done their work, and which if they persist may give rise to new growths. Dr. Beatson's theory was that the cancer growth was due to a return to activity of the germinal epithelium. In all cells there was a certain reproductive power which became lessened by the specialisation of the cells; but after this specialisation subsided the reproductive activity might re-awaken. It had seemed to him possible that in the case of the breast actual germinal cells might be present derived from the ovary. Further, the influence of removal of the ovaries on osteomalacia led him to think that it might be possible by the same means to influence the spread of cancer. He also employed the thyroid extract because of the well-known influence of this substance on lymph channels and spaces, by means of which the extension of cancer took place. His later cases included five cases of cancer of the breast and four of uterine cancer, but with these the results had not been satisfactory. His conclusions were, that early and wide removal of the growth was the proper treatment for cancer; if recurrence took place removal of the ovaries and tubes might be tried if the patient were young; if near the menopause he should in

Hosted by Google

addition give thyroid extract, but if secondary deposits had occurred he regarded further treatment as useless.

The PRESIDENT thought that the plan of treatment they had just heard described might be well worth a trial in certain cases.

Mr. MARMADUKE SHEILD remarked that cancer generally occurred at or about the menopause, when the ovaries ceased to be active; but he thought it might be logical to remove the ovaries in the case of younger women, especially because cancer growth was always much more rapid in such cases. He had been asked to tell them something of the method of treating cancer by Coley's fluid. His own experience with it was limited to four cases, two of carcinoma and two of sarcoma; but he had closely observed cases treated by others. Coley's fluid was a preparation derived from a cultivation of the bacillus prodigiosus; the cultivation was filtered so as to give a sterile fluid. The idea was derived from an observation by Fehleisen, that certain growths disappeared under an attack of erysipelas, an observation confirmed by others. But sometimes the reverse might occur, and he had known two cases at St. George's Hospital where erysipelas attacked a carcinoma of the breast with a fatal result. His four cases with Coley's fluid were as follows:—1. Recurrent carcinoma of the breast. He injected with three minims of Coley's fluid on three occasions, but it made the patient very ill, and she would not go on with the treatment. 2. Tumour of the breast, with a clinical character of scirrhus. The patient would not consent to operation. Electricity had been tried. He gave injections four times, with the same result as in the first case. 3. Sarcoma of the thigh. The growth increased and broke down, and masses soon appeared in the abdomen. 4. This was also a case of sarcoma. The nodules disappeared under the injections, but, apparently from necrosis, they were not absorbed. The patient died from pyæmia, and general deposits were found in the body, the organism being the staphylococcus. He was inclined to agree with the opinion of Mr. Butlin, who had found the fluid of limited use in sarcoma, but of no use in carcinoma. In Dr. Coley's last letter he limited its application to cases of spindle-celled sarcoma, a variety which was apt to retrogress, especially when inflamed. Coley's fluid probably acted by setting up inflammation, and he believed that injection of tuberculous and similar substances might have the same effect.

The discussion was then adjourned.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

THE sixth meeting of the session was held on March 10th in the medical library of University College, Dr. AUST LAWRENCE being in the chair.

Dr. B. J. BARON showed a patient with Web in the Larynx due to thyrotomy for removal of growths on the vocal cords.—Dr. P. W. WILLIAMS made remarks on the case.

Mr. MORTON showed the following patients with: (*a*) Charcot's Disease of the Hip-joint, (*b*) Subclavian Aneurysm, (*c*) Hypospadias, (*d*) Large Fatty Growth in the Thigh, (*e*) Papilloma of the Tongue, and (*f*) several Nodules on the Dorsum of the Tongue associated with General Leucoplakia.

Dr. MICHELL CLARKE showed the following patients with: (*a*) Athetosis, and (*b*) Amyotrophic Lateral Sclerosis.—Dr. E. L. FOX remarked on the cases.

Mr. HARSANT showed a specimen of Stricture of the Œsophagus in which gastrostomy was successfully performed.—Mr. FIRTH, Dr. P. W. WILLIAMS, and Dr. AUST LAWRENCE spoke on the subject.

Professor FAWCETT showed the following anatomical specimens: (*a*) Skull with Complete Absence of the Left Lateral Sinus, (*b*) Michel's Diverticulum, (*c*) Five Months' Fœtus showing the Position in its Membranes, (*d*) Brain Convolutions, &c., (*e*) Coloured Dissections mounted in plaster-of-paris, (*f*) Model of Deep Abdominal Viscera, and (*g*) Dissection of an Anencephalous Monster.—Mr. HARSANT remarked on the specimens.

Dr. NEWNHAM showed a specimen of Ruptured Tubal Pregnancy successfully operated on.—Dr. AUST LAWRENCE, Dr. W. C. SWAYNE, and Dr. J. G. SWAYNE spoke on the subject.

Dr. AUST LAWRENCE showed a similar specimen.

Mr. C. W. J. BRASHER read a paper on Division and Ligature of the Vasa Deferentia for Prostatic Hypertrophy in a patient aged eighty-seven years.—Mr. PAUL BUSH related a similar case, and Mr. MORTON discussed the operation.

Mr. MUNRO SMITH read a paper on Dislocation of the Peroneus Longus treated by Operation.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Tubercle.

A SPECIAL meeting of this society was held on March 12th, the President, Dr. GODFREY CARTER, being in the chair.

The occasion of the meeting was an address by Mr. Watson Cheyne on Tubercle, with especial reference to tuberculous joints. The address was profusely illustrated by a series of very beautiful lantern slides, showing the histological character of the tuberculous change in the tissues and also a number of sections of tuberculous bones and joints bearing specially on their surgical treatment. The lecturer, having given a short account of the history of a tubercle and the changes which take place in the tissues surrounding it, showed that only a small proportion of the affected structures contained tuberculous material, and that when this small proportion had been dealt with the merely inflamed tissues would, under favourable circumstances, regain their normal condition. He pointed out the important bearing of this fact on the surgical treatment of tuberculous joints, and condemned strongly the formal excision of joints in young people, as opposed to the careful erasion of all tuberculous material from such joints, the likelihood being that by excision the epiphyseal line would be interfered with and subsequent growth of the bone rendered impossible. Mr. Watson Cheyne touched shortly on the treatment of tuberculous joints by extension, and said that the extension was not intended to drag the bones apart, but merely to tire out the muscles, whose contraction would tend to keep the diseased surfaces in contact. He also spoke favourably of the treatment by injection with iodoform emulsion. In conclusion he expressed the very decided opinion that the bacillus was the one cause of the tuberculous change and showed a representation of typical tuberculous disease in the limb of a goat in which a culture of the tubercle bacillus had been injected into the nutrient artery of the bone.

A discussion followed, in which Mr. PRIDGIN TEALE, Dr. JALLAND, Mr. LITTLEWOOD, Professor TREVELYAN, Dr. RABAGLIATI, Mr. HORROCKS, and others took part.

About fifty members and visitors dined together after the address.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Gastric Ulcer.—Fruit of Cream of Tartar Tree.—Exhibition of Cases and Specimens.

A MEETING of this society was held on March 5th, Mr. J. W. TEALE, President, being in the chair.

Dr. BARRS reported two cases of Gastric Ulcer in young women presenting points of special interest mainly in the methods of treatment adopted. The first case was admitted to the hospital for profuse and repeated hæmatemesis; at one time the profound anæmia placed life in the most obvious danger, but at the end of four days the patient was taking scraped beef, and at the end of six days later was eating ordinary diet without discomfort. In the beginning ordinary methods of treatment had been adopted, including the use of nutrient enemata and suppositories, but these had to be abandoned at the end of twenty-four hours on account of the great distress which their use entailed and the rectal discharge which they set up. Dr. Barrs expressed the opinion that the so-called nutrient suppositories and enemata had little or no nutritive value, and stated his entire disbelief in the existence of any digestive power in the rectal secretions or contents. The chief indication for treatment in such cases as that described

Hosted by Google

consisted in the administration, either by the mouth or by the rectum or by both, of sufficient water to keep the patient free from thirst (usually a most urgent symptom in profuse hæmatemesis) and to abstain from all attempts at feeding until the patient is able to take solid food by the mouth without pain or vomiting, when well-cooked meat is probably the most valuable and most easily digested aliment. In the second case it was feared that perforation had taken place, and the abdomen was opened between the umbilicus and the ensiform cartilage, but no evidence of peritonitis could be found. The wound was closed, and the patient, surgically speaking, made an uninterrupted recovery; but she still suffered from a certain amount of pain after food and occasional vomiting, with slight hæmatemesis. The operation was justified by the signs that were present, but perhaps the occurrence of profuse hæmatemesis ought to be regarded as strongly negativing the likelihood of perforation at the same time.

Dr. SHARP showed a specimen of the Fruit of the Cream of Tartar Tree from the Transvaal, and said it was stated in text-books that the cream of tartar tree was Adansonia Gregorii, a native of Northern Australia, but it was not possible to say, in the absence of leaves, &c., whether his specimen belonged to this species or to Adansonia digitata, which is a native of Africa, and is called the baobab, monkey bread, or Ethiopian sour gourd. The fruits of both Adansonia digitata and Adansonia Gregorii have a very similar composition. The extract of the leaves of the former evidently contains an agent which checks excessive perspiration, the pulp of both species is employed as a remedy in dysentery, and the juice expressed from the pulp is used as a drink in the fevers which prevail in the districts. Two German observers found tartaric acid and cream of tartar in the pulp, but there seems some doubt as to the species, while an English observer, whose specimen was also doubtful as to species, found chiefly acid malate of potassium. Dr. Sharp said he owed the specimen to the kindness of Mr. Richard Reynolds.

Dr. HELLIER showed a case of Tetany in a woman, aged twenty-nine years. Five years ago, when near the end of her second pregnancy, labour was brought on by a fright. Since then she had suffered at frequent intervals from attacks of painful tonic contractions of the wrists and elbows, the fingers being extended and adducted. The attacks last eight or nine hours, and she is rarely free for two or three weeks. The flaccid muscles contract on percussing the facial nerve (Chovstek's symptom).

Dr. BRONNER showed a Knife in shape resembling a sharp-edged ophthalmic tenotomy hook with a probe point, which he used for slitting up tonsils, the probe end being inserted into the distended follicles.

Mr. LITTLEWOOD showed an old case of Trephining. The patient was a male, aged nineteen years. In June, 1893, he was trephined over the left Rolandic area a month after a fracture of the vertex. He made a good recovery, and did hard work until June, 1896. He then fell ill with vomiting, headache, nystagmus, and weakness on the right side, and was under medical treatment until January, 1897. As he made no improvement and appeared to vomit everything, an operation was decided on. Mr. Littlewood turned down the old flap and exposed the trephine opening; it was about two inches in its longest diameter, and was closed with firm fibrous tissue. This membrane was cut through near the bony margin except at the lower part, and separated from the brain, to which it was adherent over an area of about one and a half inches in diameter, and replaced without stitching, so as to allow the brain to bulge through the opening. The scalp flap was stitched over this. The patient made a good recovery, and has not vomited since the operation. Mr. Littlewood remarked that it was difficult to understand why the operation had succeeded in such a remarkable way.

The following cases and specimens were also shown:—

Dr. NUNNELEY: (1) Case of Optic Neuritis, and (2) case of Pulsating Exophthalmos.

Dr. TREVELYAN: (1) Tremor of the Right Arm, and (2) Sections of Cerebral Tumour.

Mr. LAWFORD KNAGGS: Cæcum and Appendix, the latter having sloughed.

Dr. CHURTON: (1) Case of Enlarged Spleen, and (2) case of Syphilitic Spinal Meningitis.

Dr. WHITEHEAD: Microscopical Preparations of (1) Sarcoma of the Choroid, and (2) Glio-sarcoma of the Retina.

MIDLAND MEDICAL SOCIETY.

Mediastinal Tumour.—Resection of Colon.—Spinal Caries.

A MEETING of this society was held on March 3rd, the President, Dr. A. H. CARTER, being in the chair.

The PRESIDENT showed a case of Mediastinal Tumour in a man aged fifty-five years. The sole pressure signs were intense venous hyperæmia of the head and face, coupled with prominence of the superficial veins of the neck and the arms, more particularly the right arm. The diagnosis lay between aneurysm and tumour; if the latter, probably lympho-sarcoma.

Mr. F. MARSH showed a woman, aged thirty-two years, who was admitted into the Queen's Hospital, Birmingham, on July 22nd, 1896, for Chronic Intestinal Obstruction of five months' duration, which, however, had been complete for ten days. The abdomen was tympanitic and very tender to manipulation. Nothing definite could be detected by external, rectal, or vaginal examination. Enemata having failed to give relief, an exploratory opening was made in the middle line of the abdomen on July 24th, and a constricting growth was felt in the upper part of the sigmoid colon. The median incision was therefore closed and a second was made in the usual site for iliac colotomy. With a little difficulty a loop of the sigmoid colon with the part involved was brought out through the wound, and fixed, after the manner first described by Mr. Marsh in 1890, by passing a glass rod through the meso-colon. The following day a small opening was made in the colon above the constrictions to permit the escape of flatus and liquid fæces, and on July 31st the whole of the protruding loop with the growth was removed with the thermo-cautery. Owing to the yielding of adhesions in the lower angle there was after the final severance smart hæmorrhage from a large mesenteric vessel, which was stopped by pressure forceps left on to prevent the lower segment of colon from slipping back into the abdomen. The patient made a rapid recovery and left the hospital eighteen days later with a very satisfactory artificial anus. The growth was a large annular adenoid carcinoma. As the patient was in a collapsed condition at the time of the operation, and the abdomen and intestines were greatly distended, Mr. Marsh thought it wise to wait for a few months before performing an intestinal anastomosis. On Nov. 10th the patient was re-admitted, and on the 20th an elliptical incision was made round the artificial anus, which had become much contracted and indurated, and the tissues with the ends of the colon were excised. The lumen of the lower segment had considerably diminished from disease, and there was little difficulty in inserting the largest size Murphy's button, which was used to approximate the two ends. There was no recurrence either locally or in the abdominal glands. The button was felt in the rectum and was extracted on the eleventh day. The patient steadily gained weight after the colectomy and had no difficulty with the action of the bowels since the anastomosis. She is now in robust health.

Mr. JORDAN LLOYD read a paper on Practical Observations on the Symptoms, Diagnosis, and Treatment of Spinal Caries. He referred to the variability of the cardinal symptoms and deformity, rigidity, and pain in the several regions of the spine, and described the best methods of examining the vertebral column in its different parts. He thought that Sayre's plaster-of-paris support gave the best results in the majority of cases, and insisted on the advantage of recumbency as far as was consistent with good general health in all cases. He thought chronic abscesses were best left alone until they came quite near to the surface, and referred to a series of cases of laminectomy for paraplegia attended with the best results.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on March 11th, the President, Mr. RECKLESS, being in the chair.

A letter from Lord Lister in acknowledgement of a resolution of the society congratulating him on his elevation to the Peerage was read and ordered to be entered on the minutes.

Dr. PORTER showed: (1) A case of Lead Poisoning with

Hosted by Google

fine general tremor like that of disseminated sclerosis; and (2) a case of Lateral Sclerosis.

Dr. BURGESS showed: (1) A case of Syphilitic Laryngitis; and (2) two cases of Muscular Atrophy.

Dr. ANDERSON demonstrated the method of Serum Diagnosis of Typhoid Fever. He showed under microscopes (1) a hanging drop culture to which serum from a patient suffering from typhoid fever was added; and (2) a similar hanging drop culture to which serum from a healthy person was added. He referred to the researches of Pfeiffer, Gruber, and Durham, and pointed out the bearing of their observations on the later work of Widal and Grünbaum. He described the microscopic and macroscopic methods of observing the re-action, and showed capillary tubes illustrating the latter method. He insisted on the necessity of avoiding contamination in the collection and examination of the blood, and thought it was always better to obtain a clear serum, which was most easily done by collecting the blood in sterilised pipettes and blowing it into a sterilised test-tube, as Durham suggested. It was necessary to dilute the serum, but more extended observations were required to fix the limit of dilution and the time-limit of observation by the re-action. Bacilli from old agar cultures were very rapidly agglomerated by typhoid serum and even more powerfully affected by normal blood than young growths twenty-four hours old. With very virulent cultures the re-action is delayed. Dr. Anderson had examined thirty-five cases; twenty-nine were clinically typhoid fever, and of these twenty-seven gave the re-action within half an hour, but in two the re-action was incomplete after twenty-four hours. Three cases of acute lobar pneumonia, one of pleurisy, and two of gastritis gave no re-action.—The PRESIDENT, Dr. HARGREAVES, Dr. RICHARDS, and Dr. BURGESS made remarks.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held on March 11th, the President, Mr. WILLIAMSON, being in the chair.

Dr. MCDONALD showed a man whose abdomen had been opened in Hamburg for an Abscess following Dysentery, but there seemed to be no positive evidence of its hepatic origin. He went home apparently recovered, but a month later was attacked with a violent pain in his right side, when he developed a swelling in the hepatic region and a typical pus temperature. The abscess was opened in December and characteristic chocolate-coloured pus escaped. The patient had recovered, but at the site of the first incision a hernia formed into which the stomach had prolapsed. Troublesome gastric symptoms now existed for which a third operation was required.

Dr. MCDONALD next showed three children operated upon for Tuberculous Peritonitis. The fluid had been washed out, adhesions broken down, and the wound sutured without drainage. All had made good recoveries.

Dr. MCDONALD also showed a woman whose Breast and Axillary Contents were Excised in January, 1895. She was operated upon for recurrence three times subsequently, and was free from any local growth. She presented the swelling over the sternum characteristic of bone-marrow infection and had pain in her lumbar spine.

Professor GEORGE MURRAY showed typical examples of Exophthalmic Goitre and of Spleno-medullary Leukæmia.

Mr. PAGE showed a girl twelve years of age who when ve years old had suffered from Tabes Mesenterica. She recovered, and, though not robust, had not been ill since. Nine days before admission into the infirmary she was suddenly seized with abdominal pain and developed peritonitis. She was admitted with a large pericæcal abscess, which was incised and drained. For two days she was much relieved and promised well, but on the fourth day her condition again became critical. She was in great pain; her abdomen was much distended, neither flatus nor fæces had passed for two days, and she frequently vomited fluid with a distinct fæcal odour. A small opening was made in the middle line below the umbilicus; the first distended coil was drawn out and a Paul's tube was secured in it. The vomiting ceased at once, and for more than a month the evacuations all escaped by the fæcal fistula. This had closed up spontaneously. The bowels were now acting regularly by the natural channel and the patient was well.

Dr LIMONT showed several patients with skin disease, including cases of Rodent Ulcer, a case of the Band Form of Morphœa in a child causing great deformity and incapacity, and a case of Universal Seborrhœic Dermatitis of fourteen years' duration nearly well after a month of treatment.

Mr. RUTHERFORD MORISON showed a patient, together with a Skiagram of his Forearm, which had been recently Fractured between the Pronator and Supinator Muscles. The arm was much disabled, as the power of supination was markedly diminished. He also showed a dissected specimen of a similar fracture which illustrated the Pronation of the Lower Fragment of the Radius and the Supination of the Upper.

Dr. DRUMMOND showed a woman, fifty-four years of age, with Dulness and Pulsation under her Manubrium Sterni and a Pulsating Swelling extending into the Neck. The patient had no dyspnœa such as could scarcely fail to be produced by direct pressure on the trachea if a large aneurysm existed in this situation. The diagnosis was fusiform dilatation of the aortic arch and high origin of the innominate.

Dr. DRUMMOND also showed a man who had partaken freely of all kinds of liquor, and was admitted into the infirmary a month ago with Advanced Œdema affecting his whole body surface (alcoholic œdema). Everywhere his skin pitted deeply on pressure, and in addition he was in a dazed mental condition. There was no albumin in his urine, and beyond the cardiac feebleness and dilatation due to alcohol he had no heart affection. With rest, nourishment, and abstinence from alcohol he was now almost well mentally and bodily.

Mr. OUSTON showed a series of cases illustrating varieties of inflammatory diseases of the Maxillary Antrum. He advocated an opening above and behind the apex of the socket of the right canine tooth, the patency of which was to be maintained by a lead style worn as long as necessary.

Mr. OUSTON also showed a young woman whose symptoms had commenced after a serious illness, probably Typhoid Fever. Fourteen years before she had complained of gradually increasing dyspnœa and had paroxysms threatening life. Laryngeal examination showed complete abductor paralysis; tracheotomy had been performed, and she was now entirely relieved, but it seemed probable that she would be permanently dependent on the tube. No cause could be found or explanation given for her condition.

EDINBURGH OBSTETRICAL SOCIETY.

Extra-uterine Gestation.—Substitute for Forceps.—Electro-negative Puncture in the Treatment of Fibroids.—Fœtal Malformations.

A MEETING of this society was held on March 10th, Dr. ALEXANDER BALLANTYNE, President, being in the chair.

Dr. BERRY HART read a paper on the Extra-peritoneal Incision in Extra-uterine Gestation Intact and at Mid-term. While the conditions of an extra-uterine gestation may be very varied, there are practically three possibilities in intact forms. In the first two months the gestation is in the Fallopian tube, and intact or ruptured. At the third month it begins to develop between the layers of the broad ligament and lose its pediculated characteristic. At the fourth and fifth months it is usually embedded in the pelvic connective tissue and broad ligament, and may go on developing extra-peritoneally, but as a rule the fœtus escapes into the peritoneal cavity and the placenta remains extra-peritoneal or tubal. He specially referred to the second variety, having operated on five such cases. The first case had ruptured before operation and the patient died subsequently; the others recovered. The treatment should be wholly operative. In this class of case—mid-term and intact—the gestation is extra-peritoneal; the possibility of its being an ovarian pregnancy is most remote, and primary intra-peritoneal gestation is a myth. Dr. Hart advocates extra-peritoneal incision where possible, immediate removal of the fœtus, and, to avoid bleeding, the tamponade of the sac till the placenta is thrombosed if it cannot be easily separated. He thinks it better to open the abdomen in the middle line first, and thus to find the relations of the gestation and the reflection of the peritoneum. The vaginal route for operation is more difficult if the fœtus and placenta are present, and control of hæmorrhage is very difficult, as the tampon cannot be so effectively applied.

Dr. J. W. BALLANTYNE communicated a paper by Dr. C. F. Ponder (Kalimpong) on the Action of Midwifery Forceps. He believed that, apart from pelvic deformity,

Hosted by Google

fœtal hydrocephalus, or similar conditions, the main cause of difficulty in labour was in the non-dilatability of the soft structures of the pelvis, and he advocated the use of an instrument which would dilate the soft parts and make way for the head; he would give it the name of "dilating sector."

Dr. F. W. N. HAULTAIN read a paper on Electro-negative Puncture in the Treatment of Fibroids, a record of three cases. The first patient was thirty-six years of age and had suffered for many years from a large uterine fibroid. The hæmorrhage had so reduced her that her appendages were removed. The operation did not arrest the hæmorrhage, the tumour continued to increase, and her condition went from bad to worse. Pressure symptoms were developed, with retention of urine and albuminuria, and pains in the back and cramp in the legs. She was not free from pain except under morphia; ergotin and other medicinal treatment were used. Hysterectomy had been recommended, but before this was resorted to it was determined to give a trial to electric treatment. Dr. Haultain adopted negative electro-puncture through the posterior vaginal wall, the tumour filling the true pelvis. A current of 150 milliampères was passed without great discomfort. In a week a second application was made, and two days afterwards she was entirely free from pain. Applications were made at first at weekly intervals, and afterwards twice a week. In all twenty applications were made. There was some relapse from fatigue, but another course of treatment was given, when the tumour was found to have passed into the abdominal cavity, and the cervix could be reached with ease. Intra-uterine positive electricity was then commenced. For many months she has been in good health, menstruating regularly, and the tumour was diminished and moveable. The second patient was unmarried, was thirty-eight years of age, and also suffered from retention of urine. A large solid mass was found in the pelvis and reached above the umbilicus. It could not be pushed above the brim, even with the patient anæsthetised. Electro-negative puncture was made and a current of 180 milliampères passed. Micturition was spontaneously accomplished the same day. Fifteen other applications were made, and the tumour had then so diminished in size that an intra-uterine treatment could be carried out; fifteen applications of the negative pole in this position were made. The patient was seen recently, after an interval of over three years, and was in perfect health, with the tumour of the size of a small cocoanut and freely moveable with the uterus. The third patient was forty-six years of age, and suffered from complete urinary retention. A large tumour was found impacted in the pelvic brim. After three electro-negative punctures the retention was cured. In carrying out this treatment the vagina is thoroughly disinfected and cocaine is applied to the seat of puncture. The puncture is made by means of a thin steel electrode, insulated to within three-eighths of an inch of its point. This is inserted by a rotatory movement through the vaginal wall for at least one and a half inches into the tumour. The current is completed by the usual abdominal pad, and a continuous current of from 120 to 200 milliampères passed for from five to ten minutes. After withdrawal the vagina is again syringed and a pledget of iodoform gauze applied for forty-eight hours. This form of needle and the antisepsis prevent the putrid sloughing of the tumour previously met with in this method of treatment. Electricity is a conservative measure, and with the means detailed in this paper has no mortality. It has a decided curative action in some cases. It in no way increases the danger of subsequent operation, and in the large proportion of cases it should be employed before resorting to serious surgical interference.

Dr. J. W. BALLANTYNE showed photographs sent by Dr. Michin of Charkow, Russia, illustrating two cases of Thoracopagous Double Monsters, one of a Fœtus Dicephalus Tribrachius Tripus, one of Pelvis Fissa and Ectopia Vesicæ, three of Hemicephalus, and one of Mikromelus. All these cases were from the Charkow clinic.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Nephro-lithotomy and Nephrectomy.

A MEETING of this section was held on March 5th, Mr. WILLIAM THOMSON, President, being in the chair.

Mr. MYLES read a paper on Nephro-lithotomy and Nephrectomy. Having given details of several cases of successful operations for removal of renal calculi, he drew attention to one case in which nephrectomy for renal abscess had been performed and the kidney explored with the finger, but no stone detected. Subsequently the kidney was removed and was found to contain a calculus about the size of a hazel-nut and to consist of a series of abscess cavities. One case mentioned was operated on from the loin for the purpose of fixing a floating kidney, but on exposure the kidney was found to be cystic and it was accordingly removed. The mobility probably caused the cysts by intermittent blocking of the channel through kinking of the ureter. Mr. Myles then discussed the advisability of needling the kidney for exploratory purposes from the loin, as a substitute for lumbar or abdominal exploration, and pointed out the difficulties and dangers of the operation. He next detailed his attempts to obtain Roentgen photographs of stone in the kidney, and showed the practicability of the idea by exhibiting a photograph of a cadaver in the kidney of which he had placed a large renal calculus.

The PRESIDENT said that with regard to the question of needling as an aid to diagnosis he did not believe in sticking a needle into the loin in the hope of finding the kidney or of hitting a stone.

Mr. BALL said that in experimenting with the x rays one ought to be cautious in drawing conclusions as to the presence of a stone. From the photographs which Mr. Myles exhibited it could be seen that some calculi gave photographs like those given by gall-stones, which are very transparent. The skiagraph was of no use, he said, in cases of cholesterine calculi. Calculi containing a large quantity of lime or phosphate gave a good skiagraph; but lithic acid was almost as transparent as cholesterine.

Mr. M'ARDLE thought the x rays of great value in the diagnosis of calculi. He had experimented with tubes somewhat different from the usual kind, and had found that cholesterine crystals were shown very clearly, so that the question of translucency was of no weight at all. With regard to needling, he had himself practised it as well as passing sutures through the kidney in his first operations on floating kidney, but he had now abandoned the practice as the results had been unfavourable.

Mr. R. LANE JOYNT said that from skiagraphy negative results were sometimes obtained. With reference to the case at present in hospital to which Mr. Myles had referred, the shadows on the first plate, though definite, could not be recognised as any known objects. A second photograph showed the ilium, but not the spine, and was therefore rejected. A third photograph revealed the spinal column distinctly, but no calculus was evident. He therefore concluded that, at all events, an opaque calculus was not present, but that a translucent calculus might be present.

SECTION OF OBSTETRICS.

The Anticipation of Post-partum Hæmorrhage.

A meeting of this section was held on Feb. 12th, Mr. HORNE being in the chair.

Dr. LOMBE ATTHILL read a paper on the Anticipation of Post-partum Hæmorrhage. He advocated the exhibition of ergot in combination with doses of from five to ten drops of liquor strychniæ for two or three weeks prior to the date at which labour was calculated to set in in the case of patients in whom a tendency to post-partum hæmorrhage was known to exist, and he gave the details of cases in which this treatment was followed by the most satisfactory results. He stated that the exhibition of ergot when hæmorrhage had set in was seldom of use, because ergot to produce any permanent effect on the uterus requires to be administered at least some hours previously and the dose must be repeated at intervals of about two hours. He had for many years carried out this treatment in all suitable cases; it had never failed to produce good results, and had never caused unpleasant symptoms or injured either mother or child. So far from inducing labour to set in prematurely, the exhibition of ergot and strychnine tended to retard its onset. Thus, in the case of one patient who on several occasions had nearly lost her life from post-partum hæmorrhage, not only was hæmorrhage averted, but the term of utero-gestation was prolonged to the 293rd day, calculated from the end of the last menstrual period; while on the three previous occasions labour with her had set in on about the 270th day; and in another case, while hæmorrhage was in like manner averted, labour did not set

Hosted by Google

in till the 288th day—this patient's previous pregnancies having always terminated prematurely. Dr. Atthill also advocated the exhibition of ergot in cases of threatened abortion as being, coupled with absolute rest, the best method of preventing its occurrence.

Mr. HORNE said that he had had opportunities of seeing one of the patients to whom Dr. Atthill administered ergot for some weeks before her confinement, and he could bear out his statement that very little blood was lost. He thought that the administration of ergot before uterine action set in had very little effect. The great danger in using it was when the membranes had ruptured and the waters escaped. The tonic effect of the ergot was then likely to stop the circulation of the fœtus and cause its death.

Dr. ALFRED SMITH said that on the proper management of the third stage of labour depended the chief security against post-partum hæmorrhage. He had never had in private practice a case of post-partum hæmorrhage where the labour was otherwise normal. He had seen severe cases of it in the Rotunda Hospital when he was a student, but rarely where there was proper attendance in the third stage of labour. He frequently used Dr. Atthill's mixture of ergot and strychnine in cases of threatened abortion or miscarriage.

Dr. F. W. KIDD believed that some students acquired the habit of resorting too soon in the third stage of labour to Credé's method of expelling the placenta, and that that practice was a very prevalent cause of post-partum hæmorrhage.

Reviews and Notices of Books.

The Cell in Development and Inheritance. By EDMUND B. WILSON, Ph.D., Professor of Invertebrate Zoology, Columbia University. New York and London: Macmillan and Co. 1896. Pp. 371. Price 14*s*.

WE heartily recommend this book. There are many practitioners who have neither time nor disposition to read the larger treatises on botany or histology in which the modern views on the structure and functions of the cell are to be found in some detail, yet are desirous of following the progress of science so far as to be able to comprehend the new terms that are gradually making their way into common use in scientific treatises. In the present volume they will find an admirable exposition of the knowledge that has been acquired by the labours of a succession of keen observers during the last twenty years. In that space of time an immense mass of material has accumulated, needing much discriminative power and acumen to sift, compare, and appreciate, all which Dr. Wilson has accomplished in a very satisfactory manner. The improvement in the power of the microscope and the remarkable advances that have been made in staining the several tissues and even the several parts of a cell have led to the recognition of structure where but a few years ago none was supposed to exist. It is, indeed, highly interesting and instructive to contrast the account of the structure of a cell as given by Schleiden in 1849 with that which is taught by the modern histologist. For Schleiden the cell originated in a nucleus or cytoblast formed by the approximation of particles of mucus or cytoplasm, around which a gelatinous mass developed, the whole being enclosed in a cell wall. The only named parts were the nucleolus, nucleus, and nuclear membrane, protoplasm and cell contents such as chlorophyll, starch, oil, and crystals formed from protoplasm, and the cell membrane lined by a special layer of protoplasm named Mohl's primordial utricle. No structural features were observed by him in the nucleus. The only staining agents at his command were iodine and nitric and sulphuric acids. The structure of a cell as now given is a very different affair. The cell wall, though generally present in the cells of plants, is no longer regarded as an essential constituent, and when existent is usually almost inactive and lifeless. In many cases pores have been discovered through which bridges of protoplasm pass effecting a connexion between adjoining cells. The cell contents present a delicate reticulum or mitome composed of microsomes or granules, containing in their interspaces cytoplasm and in addition various lifeless bodies such as food granules, pigment bodies, drops of oil or water, excretory matters, and other particles, known as plastids or protoplasts, capable of growth and division. Finally, there are the curious bodies known as centrosomes, with their attraction spheres, the importance of which in the multiplication of the cell has only lately been recognised and which is still the subject of inquiry. Then in regard to the nucleus we have the plasmosome or nucleolus, the chromatin and linin network, with their karyosomes or net-knots. The reader will find a chapter devoted to the process of cell division, in which are brought together the results of all the recent researches of Reinke, Hortwig, Boveri, Erlanger, and Flemming, with a full account of the process of mitosis or indirect division, with its prophases, metaphases, anaphases, and telophases—information not hitherto readily accessible. The chemical composition of the nucleus seems to be almost as complex as its histological structure, for no less than five substances have been differentiated—viz, chromatin, composing the reticulum and net-knots; linin, including the achromatic network and the spindle fibres arising from it; paralinin, the ground substance; pyrenin or parachromatin, forming the inner mass of true nucleoli; and amphipyrenin, which is the substance of the nuclear membrane. Dr. Wilson gives a full account of the processes that have been observed in the fertilisation of the ovum, with those of oogenesis and spermatogenesis. A very interesting chapter is devoted to some problems of cell organisation in which the origin of the microsomes, the connexion between the nuclear and cytoplasmic fibres, and the nature of the chromosomes, centrosomes, and attraction spheres are discussed. He quotes and apparently coincides with Rabl in thinking that the chromosomes do not lose their individuality at the close of division, but persist in the chromatic reticulum of the resting nucleus, and that whatever be the number of chromosomes entering into the formation of a reticular nucleus the same number afterwards issue from it; whilst Boveri is of opinion that we may identify every chromatic element arising from a resting nucleus with a definite element that entered into the formation of that nucleus, from which the remarkable conclusion follows that in all cells derived in the regular course of division from the fertilised egg one half of the chromosomes are of strictly paternal origin, the other half of maternal, a view that has been supported recently by the observations of Rückert, Häcker, Herla, and Zoja. One of the chapters which will be read with much interest is that which deals with the theories of inheritance and development, and especially with those of Roux and Weismann and of Hortwig and de Vries, at the close of which the writer frankly admits that an explanation of development is at present beyond our reach when he observes: "After removing the lens of the eye in the larval salamander we see it restored in perfect and typical form by regeneration from the posterior layer of the iris, we behold an adaptive response to changed conditions of which the organism can have had no antecedent experience either ontogenetic or phylogenetic, and one of so marvellous a character that we are made to realise, as by a flash of light, how far we still are from a solution of this problem." The text is prodigally illustrated by well-executed woodcuts, which in themselves are sufficient evidence of the variety and interest of the phenomena exhibited by the cell, and only lead to the fear that in the next generation there will be a special department of cytology with its own methods of research and its own language, as it has rapidly developed its own history and bibliography, which, it may be added, the student will here find well worked up to date.

Transactions of the Ophthalmological Society of the United Kingdom. Vol. XVI. Session 1895-96. London: J. & A. Churchill. 1896. Price 12*s.* 6*d.*

THE present volume of the Transactions of this active and vigorous society, edited by its able secretaries, Dr. Habershon and Mr. Lawford, is quite equal in the value of its contents to any of its predecessors. The introductory address was delivered by Mr. Nettleship, who dwelt on the many points that still require elucidation in ophthalmological work. The Bowman Lecture was given by Dr. H. Snellen, who gave as the modest title to his interesting paper "Notes on Vision and Retinal Perception," and dealt with the question of the accuracy of the ordinary methods of testing the acuteness of vision, both in regard to the form of the object employed as a test and the degree of illumination under which it is examined. The articles contained in the volume are arranged in topographical order and, commencing with the eyelids, successively give the diseases of the conjunctiva, cornea, iris, lens, choroid, retina, and optic nerve, and intra-ocular tumours, diseases of the orbit and congenital abnormalities, whilst a considerable section is devoted to miscellaneous contributions. Amongst the more important and interesting specimens and cases brought before the society may be mentioned an example of Alveolar Cancer of the Eyelid, by Mr. Simeon Snell, which is illustrated in a plate and appears to have originated in the acini of the Meibomian glands; several cases of Films of the Cornea, illustrated in a chromo-lithographic plate, by Mr. Frost and Mr. Poulett Wells; a Uveal Cyst of the Iris, by Mr. H. Eales and Mr. W. Sinclair; an article on the Treatment of Detached Retina, by Mr. Charles Wray, which led to a record of the experience of the President, of Mr. Tweedy, Mr. Snell, Mr. Eve, and others, none showing very favourable results; Mr. Lawford, Mr. W. G. Laws, and Mr. Hartridge give accounts and coloured illustrations of Retinitis Circinata; Dr. F. M. Ogilvie describes cases of Optic Atrophy in Three Brothers; and another case of Hereditary Optic Atrophy is brought forward by Dr. R. D. Batten; Mr. Spicer records a case of Chronic Retro-bulbar Optic Neuritis, with Permanent Change in the Nerve, set up by the use of Tobacco. Mr. Treacher Collins contributes an interesting paper on Intra-ocular Tumours, which he is well qualified to discuss. Mr. Jessop has collected many cases of Exophthalmic Goitre, showing the results in regard to vision that occur when the protrusion is considerable. Perhaps the best article in the volume is one by Dr. George Bull of Paris on the Visual Effects of Refractive Error, containing numerous illustrations of the appearances seen by astigmatic patients. Dr. George Dean and Mr. C. H. Usher of Aberdeen also contribute a valuable paper on the Course of the Fibres of the Optic Nerve, chiefly drawn from observations made on the rabbit. Mr. Simeon Snell gives the result of further inquiries he has made on Nystagmus, which he shows may be acquired in other occupations than coal mining.

A Manual of Obstetrics. By W. A. NEWMAN DORLAND, A.M., M.D., Assistant Demonstrator of Obstetrics, University of Pennsylvania, &c. With 163 Illustrations in the Text and six full-page Plates. London: Henry Kimpton. 1896. Price 12*s.*

THE author's chief object in preparing this manual has been to produce "a systematic and rational presentation of the subject of obstetrics as recognised by the leading teachers of the day." He divides his work into two parts, the first dealing with what he calls physiologic obstetrics, in which the course of events is followed in a natural sequence, starting from conception and ending with the time when the child is weaned. In the second part of the work the pathological deviations from the normal type are dealt with. We observe that the measurements in the text are given on the metric system and the equivalent measurements in inches are given in brackets afterwards. Thus, the external conjugate or diameter of Baudelocque is given as being normally 20½ cm. (7·9724 in.), and we are told that this is 9¼ cm. (3 6417 in.) more than the true conjugate. We should be inclined to think this method is not likely to make it easy for the student to remember the approximate measurement. An English teacher would say the external conjugate measures about 7⅞ in., and is therefore about 3½ in. greater than the conjugate of the pelvic brim. The same kind of criticism applies to the measurements given of the fœtal skull. We observe it stated among the symptoms given as indicating hydatidiform mole that there is "a discharge of a sero-sanguineous fluid containing the peculiar vesicular growths," whereas we believe it to be extremely unusual for these cysts to be found in the discharge, except, of course, when the mole is in process of being spontaneously expelled. There are several terms and expressions that would probably excite consternation if they appeared in the examination papers at the Hall on the Embankment. We can imagine the feelings of the average candidate if asked "What is the difference, if any, between the 'alligator boy' and the 'collodion fœtus'? State what you know of 'Ectromelus,' and describe Cooke's method of treating asphyxia neonatorum." This we find to be the rapid introduction of the lubricated finger into the rectum. It is only fair to add that the danger of causing permanent rectal incontinence is pointed out.

The book is of a convenient size, the illustrations are good, and the information given is generally reliable.

LIBRARY TABLE.

Dental Surgery for Medical Practitioners and Students of Medicine. By A. W. BARRETT. Third Edition with Illustrations. London: H. K. Lewis. 1897. Price 3*s.* 6*d.*—That this small volume should have reached a third edition is sufficient proof that it has been of some value to the medical student. A perusal of its pages shows that the information given is reliable, but we cannot help feeling that much more that is useful might be added, while perhaps the portions dealing with irregularities and caries of the teeth might be curtailed. It is, of course, necessary that the medical man should be able to recognise both irregularities and caries of the teeth, but the section dealing with the treatment of these hardly perhaps falls within the scope of this class of book. In future editions we would suggest that such subjects as "lancing the gum" should be more fully dealt with, as well as the reflex disturbance which can at times be traced to dentition. Some hints and directions, too, might with advantage be added for the treatment of cases where dentures have been swallowed, and the subject of Pyorrhœa Alveolaris might certainly be more fully dealt with, as well as many other subjects on the borderland between general and dental practice.

The Spas and Mineral Waters of Europe. By HERMANN WEBER, M.D. Bonn, F.R.C.P.Lond., and F. PARKES WEBER, M.D. Cantab., M.R.C.P. Lond. London: Smith, Elder, and Co. 1896.—Physicians will be grateful to the authors of this compendious manual for having afforded them the means of estimating the comparative value of British and Continental health resorts in respect to the character of the mineral spas and baths to be found therein. The details referring to each place are brief but sufficient, affording just that amount of information that is essential whilst more competent guides could not be found. The various "waters" are grouped into the following series, to each of which a separate chapter is devoted: (1) simple or indifferent thermal; (2) common salt or muriated; (3) simple alkaline; (4) muriated alkaline; (5) sulphated alkaline; (6) sulphated and muriated alkaline; (7) iron or

Hosted by Google

chalybeate; (8) arsenical; (9) sulphur; and (10) earthy or calcareous. These descriptions are preceded by chapters in which the question of balneo-therapy is discussed from the general standpoint and the mode of life at a Continental spa is sketched. At the close of the volume, after sections dealing with table waters and marine spas, there comes a most valuable chapter in which the reader has the advantage of learning on the best authority the therapeutical indications for the prescription of a sojourn in these resorts. Needless to say that the advice is thoroughly sensible and practical. A copious bibliography is appended to the volume.

Septic Conditions of the Infantile Alimentary Canal and their Treatment. By F. W. FORBES ROSS, M.D. Edin. London: The Rebman Publishing Company. 1897. Price 7*s.* 6*d.*—The subject of this monograph is one of great interest and importance, thoroughly deserving of scientific investigation and elucidation. Yet we are constrained to admit that the author has not done justice to his theme or to himself in the manner in which he has dealt with it. His style is lacking in simplicity and it is often difficult to seize upon the precise meaning he attaches to phrases and terms, whilst the plan of the book strikes us as wanting in directness and system. Nevertheless, his aim is a commendable one, for if we understand it aright it is to impress on the profession the importance of regarding infantile intestinal derangements not so much from the anatomical side as from the etiological, and thus to emphasise the fact that most of these disorders are referable to changes of a fermentative (or, as the author prefers to term it, "septic") nature. The book, in spite of its blemishes, which may be largely rectified by careful revision in another edition, contains much that is of practical value, as, for instance, the directions for securing a pure milk-supply, the mode of feeding, and the treatment of infantile constipation and diarrhœa. Amongst intestinal antiseptics the author speaks most highly of salicylate of bismuth. The good effects of irrigation with solution of boracic acid in the treatment of ulcerative colitis are emphasised, and full directions are given for this rational plan of treatment.

Sell's Directory of Telegraphic Addresses has now become a bulky volume, and a very handy one to those who have need of the especial information which it conveys. The recent addition of the telephone numbers to the addresses still further enhances the value of the work. It is published by Mr. Sell at his offices in Fleet-street, at 18*s.* for subscribers, and 21*s.* for non-subscribers, including three additional quarterly supplements.

Australian Medical Directory and Handbook. By L. BRUCK. Sydney: L. Bruck, Castlereagh-street. London: Baillière, Tindall, and Cox. 1896. Pp. 196. Price 8*s.*—This work of reference, which made its first appearance in 1883, is indispensable for those in quest of information relative to the medical profession in our extensive Australasian possessions. It commences with an abstract of the Medical Acts in force in the five Australian colonies, Tasmania, and New Zealand, after which comes a list of public medical appointments, chiefly under the various Governments, together with the names of the holders. Next there is a series of notices of the medical and allied scientific societies and a scale of fees for medical attendance. The greater part of the book consists of the list of qualified practitioners in Australia, Tasmania, New Zealand, Fiji, Samoa, Tonga, New Hebrides, and New Guinea; it contains about 2613 names, and of these about twenty are names of ladies. The first edition of the Directory was published in 1883, the second in 1886, the third in 1892, and the present one, which is the fourth, is corrected up to September, 1896. Some reference to the colonial universities was made in the second edition, but has unfortunately been omitted in the later ones on account of the tendency of the volume to increase in bulk.

Kelly's London Medical Directory for 1897 (Kelly and Co., High Holborn) embraces the districts extending from Hounslow (west) to Barking (east), and from Croydon (south) to Barnet (north). The fulness of the entries will be appreciated by many. To those to whom a medical directory of London and the suburbs is a necessity this work will be serviceable.

The Charities Register and Digest for 1897 is to hand, and the publishers (Messrs. Longmans, Green, and Co.) announce that it will henceforward be issued annually, at the reduced price of 4*s.*, instead of at 10*s.* 6*d.* This well-known and handy volume will doubtless gain many additional friends under the new *régime*.

Herbert Fry's Royal Guide to the London Charities (33rd annual edition; Chatto and Windus) is also before us, and, being arranged on the alphabetical principle in concise form, is especially convenient for easy reference.

The Local Government Directory for 1897 is a useful storehouse of information upon many matters connected with its especial department, and in these days, when increased interest is taken in the question of local government, it may well find a place on the shelves of those who would be *au fait* with what is being done. Messrs. Knight and Co., of Fleet-street, are the publishers.

Whitaker's Directory of Titled Persons for 1897 is designed as a companion to the well-known "Whitaker's Almanack," with which it is uniform in size. The work embraces the usual contents of a peerage, baronetage, and knightage, including dowager ladies and titled issue, and is presented under a single alphabet, making it very handy for reference. An alphabetical list of country seats is also given and an extended list of the Royal Family. Published at the popular price of half-a-crown, it will undoubtedly attain a large measure of success.

JOURNALS, REVIEWS, &c.

Birmingham Medical Review.—In a paper on Some Clinical Aspects of Acute and Chronic Alcoholism Dr. T. Sydney Short gives several useful hints on such important practical subjects as the distinction between alcoholic coma and apoplexy, and the diagnosis of mental disorder brought on by over-indulgence in intoxicants; the descriptions of delirium tremens, acute traumatic delirium, and mania a potû are very graphic. Mr. J. Pietersen, medical superintendent of Ashwood House Asylum, writes on Auditory Hallucinations.

Scottish Medical and Surgical Journal.—In the opening article Dr. John Duncan (Edinburgh) describes a case in which a calculus weighing 2¾ ounces was removed from the kidney. The operation was performed on Dec. 2nd last, and the wound was quite healed on Feb. 15th. Dr. Joseph Bell (Edinburgh) writes on the relation of the trained nurse to the profession and the public. Dr. W. F. Somerville (Glasgow) discusses medical gymnastics in the treatment of disease.

Edinburgh Medical Journal.—Dr. W. Allan Jamieson contributes an article on Syphilis considered dermatologically. Several valuable papers are continued from preceding numbers of the journal, such as those by Mr. G. A. Berry on Strabismus, by Dr. R. A. Fleming on the Effect of Ascending Degeneration on the Nerve Cells of the Ganglia on the Posterior Nerve Roots, and the extracts from clinical lectures by Mr. Hutchinson. The illustrations include three full-page plates and a number of figures in the text.

Dublin Journal of Medical Science.—Dr. F. W. Kidd describes three cases of Ectopic Gestation which were under his care in 1895 and 1896; the first of the patients died on the second day after operation, but the other two recovered. Mr. Langford Symes writes on Splenic Anæmia in Children.

New Inventions.

A METAL HOSPITAL INHALER.

IN connexion with the discussion which has recently taken place in the columns of THE LANCET on the occurrence of pneumonia after operations, and the possibility of infection from the inhalers used in the administration of anæsthetics, I send particulars of the metal inhalers to which I referred in my article of March 20th. If a little care is taken in using them, and if the ordinary instincts of cleanliness are followed, I have had nothing to complain of in respect to

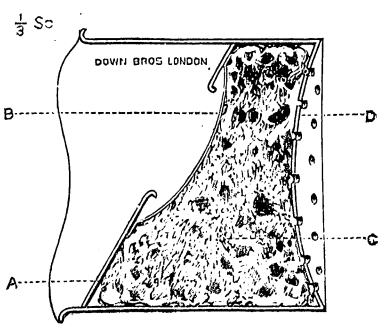

FIG. 1.

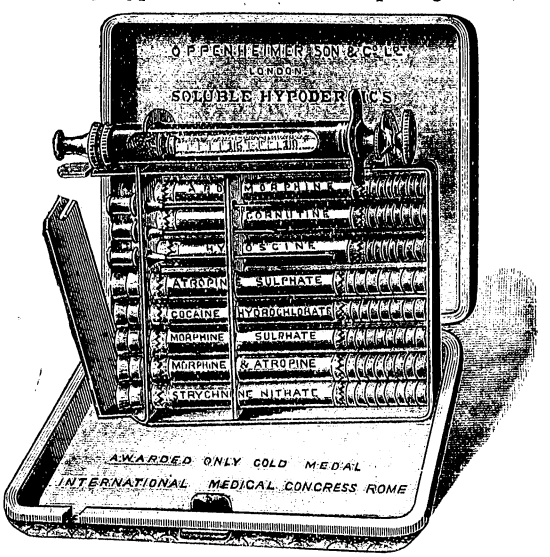
General view of inhaler.

the celluloid inhalers which I introduced some years ago; but when subjected to the rough usage of busy hospital work they are apt to get out of shape. It was chiefly to overcome this latter difficulty that these metal inhalers were designed, though it will also be found that they are more easily sterilised in accordance with the advanced theories of aseptic surgery. In general shape (Fig. 1) they resemble the Rendle's Mask, but the dome-shaped, perforated top of the latter is inverted so as to form a cup (Fig. 2, D) through which, if necessary, the sponge (Fig. 2, C) can be fed without

FIG. 2.

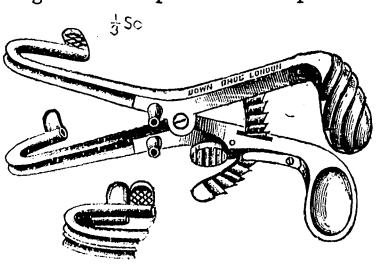


Sectional view. A. Drip-catcher or diaphragm. B. Wire sponge guard. C. Sponge. D. Perforated, concave, hinged lid.

removing the apparatus from the face. This cup is hinged to admit of the introduction of the sponge in the first instance. Another distinctive feature is the metal diaphragm (Fig. 2, A), set at an angle, and designed to prevent the superfluous liquid from running on to the face, a radical defect of many inhalers unless in skilled and careful hands. To further ensure that the sponge shall not slip on to the face a wire guard (Fig. 2, B) is fixed across the opening in the diaphragm. No flannel bag or rubber face-pad is necessary, or, in my opinion, desirable. Of course, pure chloroform ought not to be given in such an apparatus as this. It is intended, primarily, for the A.C.E. mixture, or it may be used to maintain the anæsthesia with ether. The method of using it is sufficiently obvious. I may, perhaps, add that I have had these masks in use for two or three years in hospital work, and believe that they fulfil the objects which I had in view when designing them. I am greatly indebted to Messrs. Down Bros. for their patience and skill in carrying out my wishes in the matter.

J. FREDK. W. SILK, M.D. Lond.,
Anæsthetist to King's College Hospital, &c.
Devonshire-street, Portland-place, W.

AN IMPROVED HYPODERMIC CASE.



MESSRS OPPENHEIMER AND SON, 14, Worship-street, E.C., have recently brought out a new pattern of hypodermic case which presents some useful characteristics. It is made of aluminium, is shaped like a cigarette case, and contains a moveable frame which securely holds a hypodermic syringe, two ordinary hypodermic needles, one exploring needle, and

twelve assorted tubes of soluble hypodermic tablets. In designing the case special care was taken to prevent its contents shaking about when it is carried in the pocket. The tube of any drug which happens to be required can be found at a glance. The shape and materials of the case allow of its being thoroughly cleansed and rendered aseptic whenever required by washing with any of the ordinary solutions used for the purpose.

IMPROVED MOUTH-OPENER AND GAG.

I HAVE recently designed a form of mouth-opener and gag, which, proving satisfactory in practice, I venture to recommend to the consideration of the medical profession. By the illustration it will be seen that it has a rack catch action, which fixes automatically when opening the gag, while upon touching the trigger the stop rack action is thrown out of gear and the gag closed with the greatest facility, irrespective of the amount of pressure which is being exercised upon the tooth plates. In lieu of the metal vapour tubes, as suggested by Dr. F. Hewitt, I have had a gutter cut in each of the arms of the gag, over which pieces of rubber drainage-tube may be slipped to convert them into tubes; the advantages of this are that the vapour ways do not increase the bulk and are readily cleaned or cleared, and further, being made of solid steel, they are not liable to be damaged from an accidental fall, a somewhat frequent occurrence with the metal tubes originally designed for the purpose. I have also adopted in a modified form the suggestion of Mr. W. R. Ackland—namely, that of setting the tooth plates one behind the other to act as a wedge if required. The gag can be made with broad tooth plates for edentulous jaws, or those in whom the teeth or gums are tender, thus doing away with bruising and at the same time giving a wide basis of support. The instrument being entirely of metal is easily sterilised. I have to thank Messrs. Down Bros., of 21, St. Thomas's-street, London, S.E., the makers, for much time, trouble, and careful carrying out of my ideas.

The upper figure shows the gags open. The lower shows the blades closed and the position of the tooth plates one behind the other.

THE LANCET.

LONDON: SATURDAY, MARCH 27, 1897.

WE have now before us the report of the Earl of ONSLOW'S Departmental Committee and the Memorandum of the Army Sanitary Commission on the health of the Army in India. These documents deal with an unsavoury subject for public discussion, and the public press would, no doubt, have been glad on this account to have adopted a policy of silence in regard to it, but the appalling significance of the facts was too glaring and patent to be passed over. These have now been thoroughly sifted by impartial and independent inquirers and established upon unimpeachable authority, and it is certainly time that the public should be made acquainted with them. Recognising the extreme gravity of the situation that has been brought to light, the press of this country—for the alleged condition of things in this respect has long been a source of wonder and amazement to people abroad—at once realised their sense of responsibility in the matter, and with a courage and unanimity which does them great credit have deemed it an imperative duty that the facts should not be hidden.

The Departmental Committee's very able and exhaustive report deals with the nature, extent, and the present and prospective effects of the evil. It is no wonder that the term "appalling" has been so generally applied to the facts now authoritatively set forth in regard to the free and unrestricted trade in sexual vice followed in India at the present time. What are those facts?

"The present situation," says the report, "may be summed up as follows. In 1895 venereal disease attacked the British troops in India to an unprecedented extent. The amount of syphilis was disproportionately great, and it was of an increasingly virulent type. Of the enormous total of 522 venereal cases per 1000 troops, syphilis contributed very nearly one-half—i.e., 259 cases per 1000, a figure many times greater than the highest of which we can find any record in the statistics of Continental armies for recent years, either at home or abroad. Venereal disease directly caused more than one-third of the total amount of sickness; fifteen deaths in India; 348 invalidings, resulting in 130 cases in final discharge from the service; the constant and total disablement of 3200 men out of a force of 71,000 men; and a vast amount of partial disablement and unfitness for any but routine duties. Indirectly it increased the amount of sickness and invaliding under the head of many other complaints. The military efficiency of the Army was most seriously impaired, and the increasing prevalence and intensity of contagious and inheritable disease among a body of 71,000 men, of whom many thousands are annually coming home to mingle with the civil population, was a growing danger to the health of the community."

We can only repeat here what we have already said, and the report of the Departmental Committee in effect, but in other words, confirms the accuracy of the description. The main points lie in a nutshell. We have to deal with an army composed of young, inexperienced, and inflammable material, removed from home ties and restraints, living in a state of celibacy enforced on them for the good of the State. No efforts of a direct and really practical kind are made by the State, however, to protect them against the temptations to which they are exposed, with the result that the safety of the Empire is being threatened, the health of the young soldier is being cruelly sacrificed, and the well-being of the class of society from which he is drawn and to which he may be expected to return is gravely endangered. All attempts that are made to control this class of disease by physical methods have been characterised by theorists, faddists, and fanatics as the licensing of vice, regardless of the fact that the sexual appetite is an instinct implanted in a man from his birth, though latent for some years, and that it is, and has been in all past history, the strongest passion in human nature. To recognise this is to go to the root of the matter. That no moral means of dealing with it that can be suggested should be left untried everybody will admit, but these have been practically exhausted, so far as India is concerned, with the results which we have now seen. Matters cannot be allowed to remain as they are. The State owes it as a duty to the soldier to protect him against himself and against the conditions environing him. It is clear that we cannot by merely moral means—by advice, occupation, by reading-rooms, lectures, institutes, and by physical and mental amusements—fortify him against sexual temptations. Are we, then, simply to fold our hands and shrug our shoulders? To adopt this course would be a crime and a scandal. We must deal with syphilitic disease in India as we deal with other contagious diseases that are preventable, or, at any rate, capable of being limited, and adopt some practical form of disciplinary methods and hygienic regulations for limiting their spread and for protecting our young soldiers from the disastrous results of this terrible scourge. A woman in a diseased condition plying her calling in a cantonment is a terrible calamity. Nor must it be forgotten, although it commonly is, that restrictive measures for the protection of the soldier afford the most merciful course that can possibly be adopted for the unfortunate woman. How can she be cured or relieved without rest and medical treatment? The opponents of all restrictive measures have nothing to offer as a substitute. It is only necessary that statesmen with the courage of their opinions should get up in their places in Parliament and declare that the House of Commons' Resolution must, so far as India is concerned, be rescinded. The Army Sanitary Commission, while fully recognising, as everybody must, the appalling nature of the evil, has contended that the Lock Hospital system in India failed to accomplish anything like as much as was anticipated from it, but is compelled to admit that it nevertheless served to check the growth of the evil. Many people agree with the Commission that the system which was in force and as it was worked in India proved an unsatisfactory and inadequate one, but that is no reason why another and better system cannot be devised! The authorities in India should have a free hand in considering the restrictive measures they deem essential for dealing with the disease in question.

Hosted by Google

Various suggestions and recommendations have already been put forward, and some of them are of such an obvious and common-sense character as to commend themselves to most unbiased people of ordinary intelligence; but we hope soon to have an opportunity of dealing with this side of the question. We understand that a deputation from the Royal College of Physicians of London paid a visit to Netley Hospital on Saturday last to see for themselves the cases of syphilitic disease at present under treatment there, and the results of their inspection and report upon the subject will be awaited with great interest. Meanwhile there can no longer be any doubt that it is one calling for the gravest consideration of the Government of this country with a view to prompt action being taken. We are glad to notice, too, that there seems to be a growing conviction, even on the part of those who were opposed to legislative action, that something must be done to check the evil in question, and that a disposition exists on the part of all sensible people to adopt any reasonable measures that can be applied.

THE International Sanitary Conference of Venice, after sitting for five weeks, closed its proceedings on the 19th instant, and some sixteen of the Powers represented signed the Convention which had been drawn up. Together with the three preceding Conferences—namely, those of Venice (1892), Dresden (1893), and Paris (1894)—the four Conventions which have resulted may be regarded as forming an International Code for the prevention of the dissemination of cholera and plague, both in and out of Europe, by land and by sea, and in connexion with both ordinary traffic and the pilgrimage to Mecca. The actual Convention which has been signed is not yet available, but we are informed that it will be issued from Rome after a short interval. But enough is known of it to prove that the gathering from which it has resulted has, so far as Great Britain is concerned, been a very distinct success; and when we remember that the attitude of this country has for some fifty years been one of maintained opposition to quarantine, the fact of such success means a good deal.

When the Conference was first mooted there seemed some objection on the part of Great Britain to entertain it. Plague was in a British possession, and a number of Mediterranean Powers, including, unfortunately, our own Mediterranean colonies, had set in motion the most antiquated forms of quarantine detentions, and had even resorted to absolute repulsion of every ship, person, or thing that hailed from British India. The preparation of a code for the prevention of the spread of plague under such circumstances seemed to be beset with difficulties, and on many sides nothing but failure was anticipated. But a correspondent who has had opportunities of conversing with the delegates of different nationalities during and since the sittings of the Conference has arrived at the conviction that the very eccentricities of sanitary administration which in a moment of panic were resorted to have had the effect of causing a marked change of opinion amongst some of the leading authorities of Europe in favour of the methods which have so long been adopted in England; some of these authorities have not failed to contrast the perfect quietude with which this country recently met not only an importation of a few cases of plague, but almost simultaneously the arrival of a batch of cholera cases at one of our southern ports, with the panic which was manifested in the Mediterranean—not because disease had been imported, but merely because it was thought such a thing might occur.

It is, perhaps, due to this more than anything else that sound progress has been made in Venice, and as typical of this progress we may mention the fact that shipping from British India will no longer be detained at Suez merely on the chance that someone on board may sicken of plague, but will be at once allowed to pass the canal under the care of guards, provided there is no plague on board. This in itself is a gain of the first magnitude, for the detention of ships at Suez, merely because that place is, as it has been termed, the neck of the bottle by which disease can be prevented from passing from the East into Europe, is a hindrance to British commerce and navigation of a very serious character, and one which long years of experience have shown to be quite useless. India has been styled "the home of cholera"; plague has, alas, been epidemic in Bombay for several months. But during all these years and months British shipping which passes from India to our ports in one unceasing line has always failed to convey disease to our populations, and this experience is at last telling on other nations besides ourselves. The protests which have been made by the leading medical advisers of the French Government, for example, against the attitude of Marseilles have been proved to be right. Marseilles is the main sufferer, for the shipping and merchandise which would otherwise have gone to that por have gone elsewhere, and some of the inhabitants are now crying out for Government support of those who have deprived themselves and their unhappy families of their means of existence.

Another point of importance that has been gained at Venice relates to merchandise. No country is required to prohibit the importation of any article of merchandise, and yet the failure to impose such prohibition is in no way to bring about restrictions against any such country by reason of its free admission of merchandise. Before the Conference met we heard that nearly every conceivable article might convey the infection of plague and was therefore to be avoided. Thus corn, rice, cotton, skins, Eastern carpets, and numberless other things were looked upon with suspicion and even with fear; but the Conference has not supported this view, and the result is that, whilst freedom of action within certain limits is allowed to each of the contracting Governments, every one of the articles which had been regarded as dangerous may, under the Convention, be admitted into any country at the will of the country concerned. The Governments which prefer to subject certain articles to disinfection before receiving them are, of course, free to do so; but in former Conventions there has always been a list of merchandise, produce, &c., which was either altogether prohibited of which could only be admitted after disinfection.

In short, there has been manifested a very distinct and general advance in the direction of English views. These views are that the proper way to prevent the importation and spread of disease conveyed from abroad is not to impose restrictions on ships, passengers, and merchandise, but to

Hosted by Google

improve the sanitary conditions under which the people are living, and to maintain such a sanitary administration as shall prevent the spread of any such disease as may reach our ports or cities. But Great Britain can never make any boast as to her action in this direction so long as such places as Malta follow the traditions of past generations; and we have been informed that when the action of this colony was referred to in the Conference the English delegates, for the first time in its sittings, had practically to excuse themselves for advocating that which our own colonies not only fail to carry into effect, but discard with as much tenacity as the most backward of European and other nations. Dr. THORNE THORNE is said to have announced that he felt a sense of shame, after all that the Conference had done in advocating the supersession of quarantine, that he was absolutely without answer as to the reproaches against Maltese action. Surely in this matter some change of attitude ought to be brought about, so that England shall not constantly be subjected to the reproach of other nations.

THE Council of the Hospital Sunday Fund holds its annual collection in June, on a Sunday fixed chiefly by high clerical dignitaries and ministers, on whose eloquence and on the liberality of whose congregations the sum raised mainly depends. By a concurrence of days it so happens that the Sunday chosen this year for the hospital collection synchronises with the actual anniversary of HER MAJESTY'S accession to the throne. Whether this concurrence is altogether fortuitous we cannot quite say; but of one thing there is no doubt, that it is altogether happy and natural. An esteemed contemporary of great influence has suggested that the coincidence is not a happy one and that the arrangement should be abandoned. It is argued that the public prefers to take its emotions one by one, and that it will not be in a mood, after a sermon on the reign of VICTORIA, which fills all her subjects with gratitude, to subscribe liberally to the Hospital Sunday Fund. It is doubtless our fault, but we fail to follow this reasoning. Our contemporary does not suggest any other object or collection in the place of the Hospital Sunday Fund which would be more likely to meet the mood and sympathy of the religious bodies. The subject has been already under the consideration of the Council of the Hospital Sunday Fund, which almost unanimously came to the conclusion that the Council had no option but to proceed with a collection the taking of which once a year is the object of its existence, which is generally held in June, and the date of which on this occasion has been settled at a meeting of its own constituents so far back as December. Our contemporary will readily see that it is not easy to alter an arrangement so fixed. The dates of the principal collections are all arranged months before they take place, and any dislocation would disarrange the whole method of the year. The day could not be altered merely by a vote of the Council, although it would be right to call a meeting of the constituents who really supply the Fund, and who by the rules fix the day of collection at the annual meeting in December. It is true that this course could be taken, and there can be no doubt would be taken if any good reason existed or if it could be shown that there was any real incongruity between a collection for the most benevolent of all charitable objects and a day of religious recognition of the blessings of the sixty years of the Victorian reign. The duty of the Council of the Hospital Sunday Fund is the more clear as the PRINCE of WALES has no wish or intention to apply to the various religious bodies as such or to use them as instruments for promoting his fund. There is no doubt that it is the wish of His Royal Highness that the Commemoration Fund which he has so graciously organised for the good of hospitals should interfere as little as possible with the regular channels through which the ordinary incomes of these institutions flow. And it is obvious that this non-interference with other channels will be a main test by which the public will judge of the value of the Commemoration Fund. At any rate, this is the test which will infallibly be applied by those who are responsible for the finances of hospitals. What they hope for is to receive all the ordinary income and a handsome addition from the PRINCE'S Fund. We have heard of some subscribers lessening their other subscriptions because they were contributing to the Commemoration Fund. This clearly was never intended by the PRINCE of WALES or his colleagues, and we cannot believe that it will obtain to any great extent. We trust that these considerations will suffice to convince our contemporary that the coincidence of Hospital Sunday and what must be known as the QUEEN'S Sunday is altogether a happy one. No congregation would like to separate on such a day without an offertory expressive of deep gratitude for the progress of the nation in everything that constitutes civilisation and humanity. The preachers will have no more telling point to make than the sympathy of HER MAJESTY in all the sorrows and sicknesses of her people and her constant appreciation of the progress of the healing art in making life longer and happier.

Annotations.

"Ne quid nimis."

PAYMENT OF CORONERS' JURIES.

THE absence of any means of remunerating those who form coroners' juries has long been a pressing question; it now threatens to become a burning one. At the conclusion of an inquest recently held by Dr. Wynn Westcott, at the Hackney Coroner's Court, the foreman of the jury complained that he had lost 6s. by attending. On the coroner remarking that it was a good job they did not come often he received for reply, "We come quite often enough why can't you pay us?" The coroner replied that he would, but he could not, while the county council could, but would not. This is strictly correct. According to Jervis on Coroners, fifth edition, p. 15, "There is no express provision entitling the jurors to remuneration, but in many places the authorities have allowed a fee to be paid to them." It was so formerly in a large and important northern provincial town, and we are authentically informed that in the "fifties" a long single file of "gentlemen," not only willing, but anxious, to earn the coveted shilling could be seen waiting in all weathers outside the old coroner's court, although only twelve were wanted, and their selection involved the unpleasant duty of viewing several dead bodies and of listening for some hours to the evidence.

Hosted by Google

Readers of the late Albert Smith's popular tale, "Christopher Tadpole," may remember how a medical man induced an unwilling innkeeper to receive the corpse of a man killed by an accident by reminding him of the probability that the twelve jurymen would spend twelve shillings in drinking. The incident at Hackney ought never to have occurred, and it certainly ought not to be repeated before Dr. Westcott or any other coroner. Although the coroner's court is one of first instance, and many cases begin and end there, the coroner is in the position of a judge, and to "heckle" him is as great an impropriety as to "heckle" a magistrate, a recorder, or a judge of assize. Moreover, coroners' jurors are by no means the only persons who have to suffer loss in performing a duty to their country. Medical and lay witnesses have incurred losses far exceeding the very modest sum of 6*s.* mentioned previously as incurred by the foreman, though unquestionably that was a very serious sum for a working man to lose. The debate was wound up by the coroner saying, "The matter lies in your own hands, and by combination you can get it." The matter, we fear, is not quite so simple as Dr. Westcott makes it. By the Act of 1887 a coroner's jury must comprise not less than twelve and not more than twenty-three men. Taking the very modest sum of 1*s.* per juror per inquest or even per diem, this would mean a large additional burden to the rates. Possibly the question would then arise, Why not dispense with coroners' juries altogether, as is done in many other countries, and place the coroner in the same position as the procurator-fiscal of Scotland or the *procureur* of France? The case of Matilda Clover is recent enough to remind us that our death certification is not perfect, and that a searching inquiry into all violent, unnatural, and sudden deaths the cause of which is unknown must always form an important part of our social system, and the memorable case just alluded to was a proof of the necessity of having no deaths medically certified which are not legally entitled to be so dealt with. It may appear to be a cumbrous and harsh proceeding to summon twelve men to inquire, without remuneration, into the cause of a death which after all turns out to have been a natural one; but it is not desirable that a death due to homicidal strychnine poisoning should be certified as due to alcoholism, as happened in the *cause célèbre* already mentioned. On the other hand, a coroner's jury, wisely guided by the evidence, sent to trial a wretched murderess whom a bench of magistrates had discharged on the grounds that no jury would convict. But the woman was convicted and executed.

VINOUS FERMENTATION WITHOUT YEAST CELLS.

THERE is no more interesting group of bodies in the organic world than that of the ferments. They are remarkably complex in chemical composition and possess properties of an extraordinarily energetic character. In their power to transform one substance into a new and quite different substance perhaps the action of the so-called unorganised ferments or enzymes, as, for instance, the diastase of malt or the pepsin and pancreatin of the alimentary tract, is more wonderful than when an organism is concerned. To the organised ferments belong the bacteria and germs of disease, and also yeast, the common torula. According, however, to an exceedingly interesting research carried out recently by Dr. E. Buchner, and published in a recent number of the *Berichte der Deutschen Chemischen Gesellschaft*, the transformation of sugar into carbonic acid and alcohol is not necessarily dependent upon the presence of the yeast cells themselves. Rather would the fermentation appear to be directly due to a substance contained in the cells of the nature of an unorganised ferment, an enzyme. Dr. Buchner showed that by crushing pure yeast with sand, with the addition of water, that a liquid could be expressed which, after careful filtering, was found to act on cane-sugar like yeast—that is to say, in exciting fermentation and producing carbonic acid and alcohol in the ordinary way. The addition of chloroform in small quantity does not appear to deter the action, although some precipitation of albuminous substances results. The fermentative property of this liquid is lost when it is heated to a temperature of 50° C., a point which is close to that at which the active properties of malt diastase are destroyed. The outcome of this very important investigation would seem to be that fermentation is not directly the action of a living cell, but rather the results of the action of a liquid excreted by the living organism. The precise nature of this action and the constitution of the enzyme concerned are alike far from being understood. Dr. Buchner believes the substance to be of a proteid nature, and he has proposed to call it "zymase." The importance of this discovery cannot be doubted when the application of yeast in the arts and industries is taken into consideration. It possesses, too, a very interesting bearing on the study of the vital processes. We do not doubt that before long a substance capable of exciting alcoholic fermentation will be prepared on a commercial scale, so that instead of depending upon the uncertain action of yeast cells we may have a reliable substance yielding definite products. "Zymase" should be applicable to the estimation of sugar in urine and make this method depending upon fermentation more exact, since it will exclude errors arising from the gas produced by the living cell itself or from other sources, while, still more important, the action would be due to the presence of sugar alone, and give an accurate estimate of this substance apart altogether from the presence of other reducing substances that might occur along with it.

THE BLACK WATCH.

LORD G. HAMILTON recently, in reply to a question by Sir H. Maxwell in the House of Commons, stated that the monthly returns from India showed that enteric fever had prevailed in this corps quartered at Subathu, a hill station in the Punjab on the road to Simla, during April, May, and June, increased in July, August, and September, but diminished greatly in October, and ceased in November. Lord G. Hamilton added that the report on the health of the British troops for 1896 had not yet reached him and that he would ask the Government of India to expedite it and to furnish information as to the water-supply of all the hill stations on that route—namely, Subathu, Dagshai, Kassauli, Solon, and Jutogh. The amount of enteric fever at the hill stations in India is considerable, and at several of them seems to have been increasing of late years. At Subathu there have been several outbreaks of the fever from time to time, and the medical history of the station in this respect would indicate that it is less healthy than other hill stations in the neighbourhood. The maximum prevalence of enteric fever corresponds greatly with the period of maximum heat; it rises in April and May, falls somewhat during the rainy season (monsoon), and again rises somewhat as that season ends. During the past year there has been a relative or complete absence of rain in India, with failure of the crops and famine as a consequence, and the cases have continued to occur during the whole of the hot season. There is, of course, something over and above the effects of climatic heat to account for the origin and prevalence of enteric fever; heat is only one of the factors. The greater liability of one station as compared with another to outbreaks of this fever points to the presence of some specific cause and local insanitary conditions. A water-supply derived from wells

Hosted by Google

and springs is always liable to contamination; but it is a curious fact—and we understand that it is the fact—that the prevalence of the disease is commonly greatest in the hot season before the monsoon and directly after the monsoon. The cookhouse, filters, foulness of soil from continued occupation of a site, and the state of the native bazaars have all to be taken into account, as well as the water-supply of the station.

KISSING THE BOOK.

THE Mayor of Ripon recently announced that anyone giving evidence in the County-court might, if he wished, be sworn in the Scotch form. A new copy of the Gospels was also presented to the court, and it was suggested that a bacteriological examination should be made of the cover of the old one, which had been in use for sixty years. The examination was accordingly undertaken by Mr. F. W. Richardson, consulting chemist to the Bradford Corporation. The result showed that besides various moulds there were present the micrococcus pyogenes albus and aureus, but it is comforting to know that not one of the specific germs of the communicable diseases was found. Kissing the book is a filthy and useless custom, and the Scotch form of oath-taking is, as we have over and over again insisted, infinitely preferable from every point of view.

A NEW MEDICAL CORONER.

WE are glad to be able to congratulate Dr. Lovell Drage upon his election as coroner for the St. Albans division of Hertfordshire, in succession to Mr. Brabant, a solicitor. Dr. Drage was unanimously selected by the general purposes committee of the Herts County Council. We have invariably pleaded in these columns for the principle that a coronership should be held by a medical man, and therefore it is with pleasure that we record the result of the present election. Dr. Drage and his father are both well known and esteemed practitioners in the county, and especially at Hatfield, where Dr. Drage the elder has been established for nearly fifty years, and the new coroner for some thirteen years. In addition to his recently conferred office Dr. Lovell Drage has been re-elected for the eleventh time as medical officer of health of the Hatfield district, his salary being raised by £20 per annum.

THE SCLEROGENIC TREATMENT OF TUBERCULOUS AFFECTIONS.

WE are indebted to Dr. T. Sematzky [1] for taking up and fully discussing this subject. The method of treatment, which consists of deep injections of chloride of zinc around the diseased part, was first introduced by Professor Lannelongue of Paris in 1891. During the years 1893-96 thirty cases of every variety of tuberculous disease were thus treated by him. From these, however, ten, the observation of which could not sufficiently be carried out, must be deducted. Of the remaining twenty, in ten cases highly satisfactory results were obtained, in seven fairly good ones, and only in three no effect whatever resulted. It is noteworthy, that the presence of pulmonary tuberculosis greatly reduces the chance for this local treatment. The solution used by Dr. Sematzky for these injections was of 1 in 10 strength, and according to the age of the patient from seven to ten drops were injected in a number of places (from twelve to twenty) around the periphery of the affected area. As regards the form and technique of the operation he, on the whole, followed the rules laid down by Professor Lannelongue in his first detailed communication upon the subject to the Academy of Sciences (July 7th, 1891). In some respects, however, he was forced by experience to modify them. For instance: 1. As to the time of repeating the injections, he did not wait as long as three weeks, as was recommended by Professor Lannelongue, but performed a second injection as early as on the seventh or even third day after the first injection, being guided by the indication if the pains did not cease within that period. 2. The administration of anæsthetics he regards as quite unnecessary in adults, and even in children the operation can be easily done without them, since the pain is merely that associated with all subcutaneous injections; indeed, they were slight and fugitive in character in almost all cases of his observation. 3. By observing rigid aseptic precautions the appearance of swelling, redness, and signs of any inflammatory reaction, as described by Professor Lannelongue, taking place in the vicinity of the injected area are avoided. Dr. Sematzky was accordingly able to employ an immobile dressing immediately after the injection, which proved to be exceedingly useful. The skin was first covered with collodium elasticum or traumaticin, and a solution of silicate of potash served for the immobile bandage. Professor Lannelongue's statement that this mode of treatment has no effect, or little, on the general health we find so far fully confirmed by Dr. Sematzky's record, but in the matter of the action of chloride of zinc upon tuberculous tissues he greatly differs from the first-named observer's opinion. Of course, he acknowledges the fact that it gives rise to a condition of sclerosis, but what is fatal to the existence, or at any rate paralysing to the activity, of the bacillus is, according to the writer, the great antiseptic power of which that drug is possessed. At the conclusion he remarks that this method of treatment, on account of its being very simple and easily accessible to every practitioner, deserves far more attention than it has as yet received, and if employed at an early period, and especially while the formation of granulations sets in, good results will always follow.

INFECTED WELLS AND TYPHOID FEVER.

THE corporation of Great Yarmouth has just escaped being mulcted in damages for having been the unwitting means of causing typhoid fever in the course of its prosecution of a very necessary sanitary improvement, which was intended to have a precisely contrary result. The Court of Queen's Bench was occupied for three days in hearing the evidence upon this point. It appears that in the first week of January, 1895, a new sewer was being laid down in Queen-street, and that shortly afterwards a resident in this street complained that the water in a well situated in the basement of his house was foul and that he and others had been made ill by its consumption. He attributed the contamination of the water to percolation of sewage which was alleged to have found its way into the trench dug for the reception of the new sewer. A month later the complainant, Mr. Durrant, sickened with typhoid fever, from which he died on March 1st, 1895. An action was brought by his executors claiming damages from the corporation for having through their negligence caused the pollution of the well and the death of Mr. Durrant. Without entering into the question as to whether the consumption of this water was the cause of his fatal illness or not, and even admitting this possibility, the defence went to show that the well could not have been contaminated by the temporary disturbance of the soil thirty-six feet distant, but that it was, and probably had been long, fouled by leakage from a privy situated at a higher level, only sixteen feet away. For after the well had been daily pumped out for a month the water remained still highly impure. As Mr. Justice Hawkins remarked, the poisonous contamination of the well was a singular coincidence at the time of the progress of the works, and the jury, taking a reasonable view of a question in which

Hosted by Google

their sympathies must have tended to the other side, gave a verdict for the defendant corporation. We trust that this will encourage this sanitary authority to proceed vigorously with the work of closing these wells and privies, which have long been a standing reproach to Great Yarmouth, and the existence of which is a serious danger to health. It is only surprising that typhoid fever is not more prevalent than it is in a town where facilities for the contamination of drinking-water have so long existed.

STREET NOISES.

WE offer our sincere condolences to Mrs. Dickens of Egerton-place and Mr. Smith of Egerton-crescent. These householders, in common with a number of others in London, are much annoyed by organ-grinders. They recently endeavoured to get one of these pests to move on, and when, as is the custom of organ-grinders, he refused, they gave him into custody. Now, we have little sympathy with organ-grinders, but in this case the chief offender was not the organ-grinder, but the Honourable FitzRoy Stewart, who lives at 10, Egerton-gardens. This gentleman deposed that he "had a family of young children all fond of music and, like himself, pleased to hear the organ in the street, and he gave the man 6*d*. to come and play in front of his house, out of hearing of the residents in Egerton-place; but he did not know that anyone was ill. He wished to assert the right to have musicians in front of his own house." Mr. Sheil remarked that if Mr. Stewart was so fond of organs he should have them inside his house; he then fined the organ-grinder 40*s*., which Mr. Stewart rightly enough paid. Although there seems to be, we are sorry to say, great uncertainty as to the law with regard to street musicians, there is little doubt that if Mr. Stewart continues to pay fines for organ-grinders he will find it cheaper to indulge his taste for music at some of the excellent concerts which are given in the metropolis.

RADIOGRAPHIC DERMATITIS WITH OSTITIS.
